Chapter 1

Introduction: Optimization, machine learning and convex analysis

1.1 Optimization problems in Machine Learning

Most of Machine Learning algorithms consist in solving a minimization problem. In other words, the output of the algorithm is the solution (or an approximated one) of a minimization problem. In general, non-convex problems are difficult, whereas convex ones are easier to solve. Here, we are going to focus on convex problems.

First, let's give a few examples of well-known issues you will have to deal with in supervised learning :

Example 1.1.1 (Least squares, simple linear regression or penalized linear regression).

(a) Ordinary Least Squares:

$$\min_{x \in \mathbb{R}^p} \|Zx - Y\|^2, Z \in \mathbb{R}^{n \times p}, Y \in \mathbb{R}^n$$

(b) Ridge :

$$\min_{x \in \mathbb{R}^p} \|Zx - Y\|^2 + \lambda \|x\|_2^2,$$

(c) Lasso :

$$\min_{x \in \mathbb{R}^p} \|Zx - Y\|^2 + \lambda \|x\|_1,$$

Example 1.1.2 (Linear classification).

The data consists of a training sample $\mathcal{D} = \{(z_1, y_1), \dots, (z_n, y_n)\}$, $y_i \in \{-1, 1\}$, $z_i \in \mathbb{R}^p$, where the z_i 's are the data's *features* (also called *regressors*), whereas the y_i 's are the labels which represent the class of each observation i . The sample is obtained by independent realizations of a vector $(Z, Y) \sim P$, of unknown distribution P . Linear classifiers are linear functions defined on the *feature space*, of the kind:

$$h : z \mapsto \text{sign}(\langle x, z \rangle + x_0) \quad (x \in \mathbb{R}^p, x_0 \in \mathbb{R})$$

A classifier h is thus determined by a vector $\mathbf{x} = (x, x_0)$ in \mathbb{R}^{p+1} . The vector x is the normal vector to an hyperplane which separates the space into two regions, inside which the predicted labels are respectively “+1” and “-1”.

The goal is to learn a classifier which, in average, is not wrong by much: that means that we want $\mathbb{P}(h(Z) = Y)$ to be as big as possible.

To quantify the classifier's error/accuracy, the reference loss function is the '0-1 loss':

$$L_{01}(\mathbf{x}, z, y) = \begin{cases} 0 & \text{if } -y(\langle x, z \rangle + x_0) \leq 0 \quad (h(z) \text{ and } y \text{ of same sign}), \\ 1 & \text{otherwise.} \end{cases}$$

In general, the implicit goal of machine learning methods for supervised classification is to solve (at least approximately) the following problem:

$$\min_{\mathbf{x} \in \mathbb{R}^{p+1}} \frac{1}{n} \sum_{i=1}^n L_{0,1}(\mathbf{x}, z_i, y_i) \quad (1.1.1)$$

i.e. to minimize the *empirical risk*.

As the cost L is not convex in \mathbf{x} , the problem (1.1.1) is *hard*. Classical Machine learning methods consist in minimizing a function that is similar to the objective (1.1.1): the idea is to replace the cost 0-1 by a *convex substitute*, and then to add a penalty term which penalizes "complexity" of x , so that the problem becomes numerically feasible. More precisely, the problem to be solved numerically is

$$\min_{x \in \mathbb{R}^p, x_0 \in \mathbb{R}} \sum_{i=1}^n \varphi(-y_i(x^\top z_i + x_0)) + \lambda \mathcal{P}(x), \quad (1.1.2)$$

where \mathcal{P} is the penalty and φ is a convex substitute to the cost 0-1.

Different choices of penalties and convex substitutes are available, yielding a range of methods for supervised classification :

- For $\varphi(u) = \max(0, 1 + u)$ (Hinge loss), $\mathcal{P}(x) = \|x\|^2$, this is the SVM:

$$\min_{x \in \mathbb{R}^p, x_0 \in \mathbb{R}} \sum_{i=1}^n \max(0, 1 - y_i(x^\top z_i + x_0)) + \lambda \|x\|^2.$$

- In the separable case (i.e. when there is a hyperplane that separates the two classes), introduce the "convex indicator function" (also called *characteristic function*),

$$\iota_A(x) = \begin{cases} 0 & \text{if } x \in A, \\ +\infty & \text{if } x \in A^c, \end{cases} \quad (A \subset \mathcal{X})$$

and set

$$\varphi(u) = \iota_{\mathbb{R}^-}(u).$$

The solution to the problem is the maximum margin hyperplane:

$$\begin{aligned} & \min_{x \in \mathbb{R}^p, x_0 \in \mathbb{R}} \sum_{i=1}^n \iota(-y_i(x^\top z_i + x_0)) + \lambda \|x\|^2 \\ &= \min_{x \in \mathbb{R}^p, x_0 \in \mathbb{R}} \{ \lambda \|x\|^2, \text{ st: } -y_i(x^\top z_i + x_0) \leq 0, \forall i, 1 \leq i \leq n \} \end{aligned}$$

- For $\varphi(u) = \log(1 + \exp(u))$ (Logistic loss) and $\mathcal{P}(x) = \|x\|^2$, this is the logistic regression:

$$\min_{x \in \mathbb{R}^p, x_0 \in \mathbb{R}} \sum_{i=1}^n \log(1 + \exp(-y_i(x^\top z_i + x_0))) + \lambda \|x\|^2.$$

To summarize, the common denominator of all these versions of example 1.1.2 is as follows:

- The risk of a classifier x is defined by $J(x) = \mathbb{E}(L(x, D))$. We are looking for x which minimizes J .
- \mathbb{P} is unknown, and so is J . However, $D \sim \mathbb{P}$ is available. Therefore, the approximate problem is to find:

$$\hat{x} \in \arg \min_{x \in \mathcal{X}} J_n(x) \triangleq \frac{1}{n} \sum_{i=1}^n L(x, d_i)$$

- The cost L is replaced by a convex surrogate L_φ , so that the function $J_{n,\varphi} = \frac{1}{n} \sum_{i=1}^n L_\varphi(x, d_i)$ is convex in x .
- In the end, the problem to be solved, when a convex penalty term is incorporated, is

$$\min_{x \in \mathcal{X}} J_{n,\varphi}(x) + \lambda \mathcal{P}(x). \quad (1.1.3)$$

In the remaining of the course, the focus is on that last point: how to solve the convex minimization problem (1.1.3)?

Example 1.1.3 (Hyperparameter optimization). A natural question when considering Problem (1.1.3) is: what value should λ take? One of the goals of the regularization is to improve the generalization performance of the model. Thus, we expect the model to behave well on new data points $(d_j^{\text{valid}})_{1 \leq j \leq m}$ where we will evaluate the parameters returned by the algorithm that solves (1.1.3).

We can formalize this question into a bilevel optimization problem, that is an optimization problem that involves (1.1.3) as an inner problem.

$$\min_{\lambda \geq 0} \frac{1}{m} \sum_{j=1}^m L(x^{(\lambda)}, d_j^{\text{valid}})$$

$$\hat{x}^{(\lambda)} \in \arg \min_x \frac{1}{n} \sum_{i=1}^n L_\varphi(x, d_i) + \lambda \mathcal{P}(x)$$

We will then solve a sequence of convex optimization problems indexed by λ and solving each of them fast will matter for the overall performance.

1.2 General formulation of the problem

In this course, we only consider optimization problems which are defined on a finite dimension space $\mathcal{X} = \mathbb{R}^n$. These problems can be written, without loss of generality, as follows:

$$\begin{aligned} & \min_{x \in \mathcal{X}} f(x) \\ & \text{s.t. (such that / under constraint that)} \\ & g_i(x) \leq 0 \text{ for } 1 \leq i \leq p, \quad F_i(x) = 0 \text{ for } 1 \leq i \leq m. \end{aligned} \quad (1.2.1)$$

The function f is the *target function* (or *target*),
the vector

$$C(x) = (g_1(x), \dots, g_p(x), F_1(x), \dots, F_m(x))$$

is the (functional) constraint vector.

The region

$$K = \{x \in \mathcal{X} : g_i(x) \leq 0, 1 \leq i \leq p, \quad F_i(x) = 0, 1 \leq i \leq m\}$$

is the set of *feasible* points.

- If $K = \mathbb{R}^n$, this is an *unconstrained* optimization problem.
- Problems where $p \geq 1$ and $m = 0$, are referred to as *inequality constrained* optimization problems.
- If $p = 0$ and $m \geq 1$, we speak of *equality constrained* optimization.
- When f and the constraints are regular (differentiable), the problem is called *differentiable* or *smooth*.
- If f or the constraints are not regular, the problem is called *non-differentiable* or *non-smooth*.
- If f and the constraints are convex, we have a *convex* optimization problem (more details later).

Solving the general problem (1.2.1) consists in finding

- a minimizer $x^* \in \arg \min_K f$ (if it exists, *i.e.* if $\arg \min_K f \neq \emptyset$),
- the *value* $f(x^*) = \min_{x \in K} f(x)$,

We can rewrite the constrained problem as an unconstrained problem, thanks to the infinite indicator function ι introduced earlier. Let's name g and (resp) F the vectors of the inequality and (resp) equality constraints.

For $x, y \in \mathbb{R}^n$, we write $x \preceq y$ if $(x_1 \leq y_1, \dots, x_n \leq y_n)$ and $x \not\preceq y$ otherwise. The problem (1.2.1) is equivalent to :

$$\min_{x \in E} f(x) + \iota_{g \preceq 0, F=0}(x) \tag{1.2.2}$$

Let's notice that, even if the initial problem is smooth, the new problem isn't anymore !

1.3 Algorithms

Approximated solutions Most of the time, Problem (1.2.1) cannot be analytically solved. However, numerical algorithms can provide an approximate solution. Finding an ϵ -approximate solution (**ϵ -solution**) consists in finding $\hat{x} \in K$ such that, if the "true" minimum x^* exists, we have

- $\|\hat{x} - x^*\| \leq \epsilon$,
- and/or
- $|f(\hat{x}) - f(x^*)| \leq \epsilon$.

“Black box” model A standard framework for optimization is the **black box**. That is, we want to optimize a function in a situation where:

- The target f is not entirely accessible (otherwise the problem would already be solved !)
- The algorithm does not have any access to f (and to the constraints), except by successive calls to an *oracle* $\mathcal{O}(x)$.
Typically, $\mathcal{O}(x) = f(x)$ (0-order oracle) or $\mathcal{O}(x) = (f(x), \nabla f(x))$ (1-order oracle), or $\mathcal{O}(x)$ can evaluate higher derivative of f (≥ 2 -order oracle).
- At iteration k , the algorithm only has the information $\mathcal{O}(x_1), \dots, \mathcal{O}(x_k)$ as a basis to compute the next point x_{k+1} .
- The algorithm stops at time k if a criterion $T_\epsilon(x_k)$ is satisfied: the latter ensures that x_k is an ϵ -solution.

Performance of an algorithm Performance is measured in terms of computing resources needed to obtain an approximate solution.

This obviously depends on the considered problem. A **class of problems** is:

- A class of target functions (regularity conditions, convexity or other)
- A condition on the starting point x_0 (for example, $\|x - x_0\| \leq R$)
- An oracle.

Definition 1.3.1 (oracle complexity). The **oracle complexity** of an algorithm \mathcal{A} , for a class of problems C and a given precision ϵ , is the minimal number $N_{\mathcal{A}}(\epsilon)$ such that, for all objective functions and any initial point $(f, x_0) \in C$, we have:

$$N_{\mathcal{A}}(f, \epsilon) \leq N_{\mathcal{A}}(\epsilon)$$

where : $N_{\mathcal{A}}(f, \epsilon)$ is the number of calls to the oracle that are needed for \mathcal{A} to give an ϵ -solution. The oracle complexity, as defined here, is a *worst-case* complexity. The computation time depends on the oracle complexity, but also on the number of required arithmetical operations at each call to the oracle. The total number of arithmetic operations to achieve an ϵ -solution in the worst case, is called *arithmetic complexity*. In practice, it is the arithmetic complexity which determines the computation time, but it is easier to prove bounds on the oracle complexity .

1.4 Preview of the rest of the course

A natural idea to solve general problem (1.2.1) is to start from an arbitrary point x_0 and to propose the next point x_1 in a region where f “has a good chance” to be smaller.

If f is differentiable, one widely used method is to follow “the line of greatest slope”, i.e. move in the direction given by $-\nabla f$.

What’s more, if there is a local minimum x^* , we then have $\nabla f(x^*) = 0$. So a similar idea to the previous one is to set the gradient equal to zero.

Here we have made implicit assumptions of regularity, but in practice some problems can arise.

- Under which assumptions is the necessary condition ‘ $\nabla f(x) = 0$ ’ sufficient for x to be a local minimum?
- Under which assumptions is a local minimum a global one?

- What if f is not differentiable?
- How should we proceed when E is a high-dimensional space?
- What if the new point x_1 leaves the admissible region K ?

The appropriate framework to answer the first two questions is convex analysis. The lack of differentiability can be bypassed by introducing the concept of *subdifferential*. *Duality* methods solve a problem related to ((1.2.1)), called *dual problem*. The dual problem can often be easier to solve (*ex*: if it belongs to a space of smaller dimension). Typically, once the dual solution is known, the primal problem can be written as a unconstrained problem that is easier to solve than the initial one. For example, *proximal* methods can be used to solve constrained problems.

To go further ...

A panorama in [Boyd and Vandenberghe \(2009\)](#), chapter 4, more rigor in [Nesterov \(2004\)](#)'s introduction chapter (easy to read !).

Chapter 2

Elements of convex analysis

Throughout this course, the functions of interest are defined on a subset of $\mathcal{X} = \mathbb{R}^n$. We will also need a Euclidean space \mathbf{E} , endowed with a scalar product denoted by $\langle \cdot, \cdot \rangle$ and an associated norm $\| \cdot \|$. In practice, the typical setting is $\mathbf{E} = \mathcal{X} \times \mathbb{R} = \mathbb{R}^{n+1}$.

Notations: For convenience, the same notation is used for the scalar product in \mathcal{X} and in \mathbf{E} . If $a \leq b \in \mathbb{R} \cup \{-\infty, +\infty\}$, $(a, b]$ is an interval open at a , closed at b , with similar meanings for $[a, b)$, (a, b) and $[a, b]$.

N.B The proposed exercises include basic properties for you to demonstrate. You are strongly encouraged to do so ! The exercises and chapters marked with * are less essential.

2.1 Convexity

Definition 2.1.1 (Convex set). A set $K \subset \mathbf{E}$ is **convex** if

$$\forall (x, y) \in K^2, \forall t \in [0, 1], \quad tx + (1 - t)y \in K.$$

Exercise 2.1.1.

1. Show that a ball, a vector subspace or an affine subspace of \mathbb{R}^n are convex.
2. Show that any intersection of convex sets is convex.

In constrained optimization problems, it is useful to define cost functions with value $+\infty$ outside the admissible region. For all $f : \mathcal{X} \rightarrow [-\infty, +\infty]$, the *domain* of f , denoted by $\text{dom}(f)$, is the set of points x such that $f(x) < +\infty$.

A function f is called **proper** if $\text{dom}(f) \neq \emptyset$ (i.e $f \not\equiv +\infty$) and if f *never* takes the value $-\infty$.

Definition 2.1.2. Let $f : \mathcal{X} \rightarrow [-\infty, +\infty]$. The **epigraph** of f , denoted by $\text{epi } f$, is the subset of $\mathcal{X} \times \mathbb{R}$ defined by:

$$\text{epi } f = \{(x, t) \in \mathcal{X} \times \mathbb{R} : \quad t \geq f(x) \}.$$

Beware: the “ordinates” of points in the epigraph always lie in $(-\infty, \infty)$, by definition.

Definition 2.1.3 (Convex function). $f : \mathcal{X} \rightarrow [-\infty, +\infty]$ is **convex** if its epigraph is convex.

Proposition 2.1.1. A function $f : \mathcal{X} \rightarrow [-\infty, +\infty]$ is convex if and only if

$$\forall (x, y) \in \mathcal{X}^2, \forall t \in (0, 1), \quad f(tx + (1 - t)y) \leq tf(x) + (1 - t)f(y).$$

Proof. Assume that f satisfies the inequality. Let (x, u) and (y, v) be two points of the epigraph: $u \geq f(x)$ and $v \geq f(y)$. In particular, $(x, y) \in \text{dom}(f)^2$. Let $t \in]0, 1[$. The inequality implies that $f(tx + (1-t)y) \leq tu + (1-t)v$. Thus, $t(x, u) + (1-t)(y, v) \in \text{epi}(f)$, which proves that $\text{epi}(f)$ is convex.

Conversely, assume that $\text{epi}(f)$ is convex. If $x \notin \text{dom } f$ or $y \notin \text{dom } f$, the inequality is trivial. So let us consider $(x, y) \in \text{dom}(f)^2$. For (x, u) and (y, v) two points in $\text{epi}(f)$, and $t \in [0, 1]$, the point $t(x, u) + (1-t)(y, v)$ belongs to $\text{epi}(f)$. So, $f(tx + (1-t)y) \leq tu + (1-t)v$.

- If $f(x)$ et $f(y)$ are $> -\infty$, we can choose $u = f(x)$ and $v = f(y)$, which demonstrates the inequality.
- If $f(x) = -\infty$, we can choose u arbitrary close to $-\infty$. Letting u go to $-\infty$, we obtain $f(tx + (1-t)y) = -\infty$, which demonstrates here again the inequality we wanted to prove. \square

Exercise 2.1.2. Show that:

1. If f is convex, then $\text{dom}(f)$ is convex.
2. If f_1, f_2 are convex and $a, b \in \mathbb{R}_+$, then $af_1 + bf_2$ is convex.
3. If f is convex and $x, y \in \text{dom } f$, then for all $t \geq 1$, $z_t = x + t(y - x)$ satisfies the inequality $f(z_t) \geq f(x) + t(f(y) - f(x))$.
4. If f is convex, proper, with $\text{dom } f = \mathcal{X}$, and if f is bounded, then f is constant.

Exercise 2.1.3. *

Let f be a convex function and x, y in $\text{dom } f$, $t \in (0, 1)$ and $z = tx + (1-t)y$. Assume that the three points $(x, f(x))$, $(z, f(z))$ and $(y, f(y))$ are aligned. Show that for all $u \in (0, 1)$, $f(ux + (1-u)y) = uf(x) + (1-u)f(y)$.

In the following, the **upper hull** of a family $(f_i)_{i \in I}$ of convex functions will play a key role. By definition, the upper hull of the family is the function $x \mapsto \sup_i f_i(x)$.

Proposition 2.1.2. Let $(f_i)_{i \in I}$ be a family of convex functions $\mathcal{X} \rightarrow [-\infty, +\infty]$, with I any set of indices. Then **the upper hull of the family $(f_i)_{i \in I}$ is convex**.

Proof. Let $f = \sup_{i \in I} f_i$ be the upper hull of the family.

(a) $\text{epi } f = \bigcap_{i \in I} \text{epi } f_i$. Indeed,

$$(x, t) \in \text{epi } f \Leftrightarrow \forall i \in I, t \geq f_i(x) \Leftrightarrow \forall i \in I, (x, t) \in \text{epi } f_i \Leftrightarrow (x, t) \in \bigcap_i \text{epi } f_i.$$

(b) Any intersection of convex sets $K = \bigcap_{i \in I} K_i$ is convex (exercice 2.1.1)

(a) and (b) show that $\text{epi } f$ is convex, i.e. that f is convex. \square

Proposition* 2.1.3. Let $F : \mathcal{X} \times \mathcal{Y} \rightarrow \mathbb{R}$ be a **jointly convex function**. Then the function

$$f : \mathcal{X} \rightarrow \mathbb{R} \\ x \mapsto \inf_{y \in \mathcal{Y}} F(x, y)$$

is convex.

Proof. Let $u, v \in \mathcal{X}$ and $\alpha \in (0, 1)$. We need to show that $f(\alpha u + (1 - \alpha)v) \leq \alpha f(u) + (1 - \alpha)f(v)$.

$$\begin{aligned}
\alpha f(u) + (1 - \alpha)f(v) &= \alpha \inf_{y_u \in \mathcal{Y}} F(u, y_u) + (1 - \alpha) \inf_{y_v \in \mathcal{Y}} F(v, y_v) && \text{(definition of } f\text{)} \\
&= \inf_{y_u \in \mathcal{Y}, y_v \in \mathcal{Y}} \alpha F(u, y_u) + (1 - \alpha)F(v, y_v) && \text{(separable problems)} \\
&\geq \inf_{y_u \in \mathcal{Y}, y_v \in \mathcal{Y}} F(\alpha u + (1 - \alpha)v, \alpha y_u + (1 - \alpha)y_v) && \text{(joint convexity of } F\text{)} \\
&= \inf_{y \in \mathcal{Y}} F(\alpha u + (1 - \alpha)v, y) && \text{(change of variable)} \\
&= f(\alpha u + (1 - \alpha)v)
\end{aligned}$$

A valid change of variable is $(y, y') = (\alpha y_u + (1 - \alpha)y_v, y_v)$. It is indeed invertible since we have $\alpha \in (0, 1)$. \square

Definition 2.1.4 (Strong convexity). A function f is μ -strongly convex if $f - \frac{\mu}{2}\|\cdot\|^2$ is convex.

Proposition 2.1.4. A function $f : \mathcal{X} \rightarrow [-\infty, +\infty]$ is μ -strongly convex if and only if

$$\forall (x, y) \in \mathcal{X}^2, \forall t \in (0, 1), \quad f(tx + (1 - t)y) \leq tf(x) + (1 - t)f(y) - \frac{\mu}{2}t(1 - t)\|x - y\|^2.$$

2.2 Lower semi-continuity

In this course, we will consider functions with infinite values. Such function cannot be continuous. However, some kind of continuity would be very desirable. For infinite-valued convex function, lower semi-continuity is the good generalization of continuity.

Definition 2.2.1 (Reminder: \liminf : **limit inferior**).

The **limit inferior** of a sequence $(u_n)_{n \in \mathbb{N}}$, where $u_n \in [-\infty, \infty]$, is

$$\liminf(u_n) = \sup_{n \geq 0} \left(\inf_{k \geq n} u_k \right).$$

Since the sequence $V_n = \inf_{k \geq n} u_k$ is non decreasing, an equivalent definition is

$$\liminf(u_n) = \lim_{n \rightarrow \infty} \left(\inf_{k \geq n} u_k \right).$$

Definition 2.2.2 (Lower semicontinuous function). A function $f : \mathcal{X} \rightarrow [-\infty, \infty]$ is called **lower semicontinuous (l.s.c.) at $x \in \mathcal{X}$** if for all sequence (x_n) which converges to x ,

$$\liminf f(x_n) \geq f(x).$$

The function f is said to be **lower semicontinuous**, if it is l.s.c. at x , for all $x \in \mathcal{X}$.

The interest of l.s.c. functions becomes clear in the next result

Proposition 2.2.1 (epigraphical characterization). Let $f : \mathcal{X} \rightarrow [-\infty, +\infty]$, any function f is l.s.c. if and only if its epigraph is closed.

Proof. If f is l.s.c., and if $(x_n, t_n) \in \text{epi } f \rightarrow (\bar{x}, \bar{t})$, then, $\forall n, t_n \geq f(x_n)$. Consequently,

$$\bar{t} = \liminf t_n \geq \liminf f(x_n) \geq f(\bar{x}).$$

Thus, $(\bar{x}, \bar{t}) \in \text{epi } f$, and $\text{epi } f$ is closed.

Conversely, if f is *not* l.s.c., there exists an $x \in \mathcal{X}$, and a sequence $(x_n) \rightarrow x$, such that $f(x) > \liminf f(x_n)$, i.e., there is an $\epsilon > 0$ such that $\forall n \geq 0, \inf_{k \geq n} f(x_k) \leq f(x) - \epsilon$. Thus, for all $n, \exists k_n \geq k_{n-1}, f(x_{k_n}) \leq f(x) - \epsilon$. We have built a sequence $(w_n) = (x_{k_n}, f(x) - \epsilon)$, each term of which belongs to $\text{epi } f$, and which converges to a limit $\bar{w} = (f(x) - \epsilon)$ which is outside the epigraph. Consequently, $\text{epi } f$ is not closed. \square

Lower semi-continuity is a very desirable property for a function we want to optimize thanks to the following proposition.

Proposition 2.2.2. *Let f be a l.s.c function such that $\lim_{\|x\| \rightarrow +\infty} f(x) = +\infty$. Then there exists x^* such that $f(x^*) = \inf_{x \in \mathcal{X}} f(x)$.*

Proof. Let $(x_n)_{n \geq 0}$ be a minimizing sequence, that is a sequence of \mathcal{X} such that we have $\lim_{n \rightarrow \infty} f(x_n) = \inf_{x \in \mathcal{X}} f(x)$.

Suppose that (x_n) were unbounded. Then there would exist a subsequence $(x_{\phi(n)})$ such that $\lim_{n \rightarrow \infty} \|x_{\phi(n)}\| \rightarrow +\infty$. By the assumptions on f , this implies that $\lim_{n \rightarrow \infty} f(x_n) = +\infty$ which contradicts the fact that $(x_n)_{n \geq 0}$ is a minimizing sequence.

Thus (x_n) is bounded and we can extract from it a subsequence $(x_{\phi(n)})$ converging to, say, x^* . As f is l.s.c., we get $\inf_{x \in \mathcal{X}} f(x) = \lim_{n \rightarrow \infty} f(x_{\phi(n)}) = \liminf f(x_{\phi(n)}) \geq f(x^*) \geq \inf_{x \in \mathcal{X}} f(x)$. \square

A nice property of the family of l.s.c. functions is its stability with respect to point-wise suprema.

Proposition 2.2.3. *Let $(f_i)_{i \in I}$ a family of l.s.c. functions. Then, the upper hull $f = \sup_{i \in I} f_i$ is l.s.c.*

Proof. Let C_i denote the epigraph of f_i and $C = \text{epi } f$. As already shown (proof of proposition 2.1.2), $C = \cap_{i \in I} C_i$. Each C_i is closed, and any intersection of closed sets is closed, so C is closed and f is l.s.c. \square

Exercise 2.2.1. * Show that a function f is l.s.c. if and only if its level sets :

$$L_{\leq \alpha} = \{x \in \mathcal{X} : f(x) \leq \alpha\}$$

are closed.

(see, e.g., [Rockafellar et al. \(1998\)](#), Theorem 1.6.)

2.3 Subdifferential

A classical property of convex function is that they are above their tangents. In a multi-dimensional setting, tangents become tangent hyperplanes

Proposition 2.3.1. *Let $f : \mathcal{X} \rightarrow (-\infty, \infty]$ be a convex function, differentiable in x . Then for all $y \in \mathcal{X}$,*

$$f(y) \geq f(x) + \langle \nabla f(x), y - x \rangle$$

Proof.

$$\begin{aligned} \langle \nabla f(x), y - x \rangle &= \lim_{t \rightarrow 0} \frac{f(x + t(y - x)) - f(x)}{t} \\ &= \lim_{t \rightarrow 0^+, t \leq 1} \frac{1}{t} (f(ty + (1 - t)x) - f(x)) \end{aligned}$$

For $0 \leq t \leq 1$, $f(ty + (1 - t)x) - f(x) \leq tf(y) + (1 - t)f(x) - f(x)$ so

$$\langle \nabla f(x), y - x \rangle \leq \lim_{t \rightarrow 0^+, t \leq 1} \frac{1}{t} (tf(y) - tf(x)) = f(y) - f(x) \quad \square$$

When the function is not differentiable, we generalize the notion of gradient as follows.

Definition 2.3.1 (Subdifferential). Let $f : \mathcal{X} \rightarrow [-\infty, +\infty]$ and $x \in \text{dom}(f)$. A vector $\phi \in \mathcal{X}$ is called a **subgradient** of f at x if:

$$\forall y \in \mathcal{X}, \quad f(y) - f(x) \geq \langle \phi, y - x \rangle .$$

The **subdifferential** of f in x , denoted by $\partial f(x)$, is the whole set of the subgradients of f at x . By convention, $\partial f(x) = \emptyset$ if $x \notin \text{dom}(f)$.

Interest: Gradient methods in optimization can still be used in the non-differentiable case, choosing a subgradient in the subdifferential.

Proposition 2.3.2. Let $f : \mathcal{X} \rightarrow (-\infty, \infty]$ be a convex function, differentiable in x . Then $\partial f(x) = \{\nabla f(x)\}$

Proof. If f is differentiable at x , Proposition 2.3.1 shows that $\partial f(x) \neq \emptyset$. Let $\phi \in \partial f(x)$ and $t \neq 0$. Then for all $y \in \text{dom}(f)$, $f(y) - f(x) \geq \langle \phi, y - x \rangle$. Applying this inequality to $y = x + t(\phi - \nabla f(x))$ leads to :

$$\frac{f(x + t(\phi - \nabla f(x))) - f(x)}{t} \geq \langle \phi, \phi - \nabla f(x) \rangle .$$

The left term converges to $\langle \nabla f(x), \phi - \nabla f(x) \rangle$ by definition of the directional derivative. Finally,

$$\langle \nabla f(x) - \phi, \phi - \nabla f(x) \rangle \geq 0,$$

i.e. $\phi = \nabla f(x)$. □

In order to clarify in what cases the subdifferential is non-empty, we need two more definitions:

Definition* 2.3.2. A set $A \subset \mathcal{X}$ is called an **affine space** if, for all $(x, y) \in A^2$ and for all $t \in \mathbb{R}$, $x + t(y - x) \in A$. The **affine hull** $\mathcal{A}(C)$ of a set $C \subset \mathcal{X}$ is **the smallest affine space** that contains C .

Definition* 2.3.3. Let $C \subset \mathbf{E}$. The **topology relative to C** is a topology on $\mathcal{A}(C)$. The open sets in this topology are the sets of the kind $\{V \cap \mathcal{A}(C)\}$, where V is open in \mathbf{E} .

Definition* 2.3.4. Let $C \subset \mathcal{X}$. The **relative interior** of C , denoted by $\text{relint}(C)$, is the interior of C for the topology relative to C . In other words, it consists of the points x that admit a neighborhood V , open in \mathbf{E} , such that $V \cap \mathcal{A}(C) \subset C$.

Clearly, $\text{int}(C) \subset \text{relint}(C)$. What's more, one can show that if C is convex, then $\text{relint}(C) \neq \emptyset$.

Proposition* 2.3.3. Let $f : \mathcal{X} \rightarrow [-\infty, +\infty]$ be a convex function and $x \in \text{relint}(\text{dom } f)$. Then $\partial f(x)$ is non-empty.

Proof. The proof is a bit technical and uses the concept of separating hyperplane [Bauschke and Combettes \(2011\)](#). □

Remark 2.3.1 (the question of $-\infty$ values).

If $f : \mathcal{X} \rightarrow [-\infty, +\infty]$ is convex and if $\text{relint dom } f$ contains a point x such that $f(x) > -\infty$, then f *never* takes the value $-\infty$. So f is proper.

Exercise 2.3.1. * Show this point, using proposition 2.3.3.

Example 2.3.1. The absolute-value function $x \mapsto |x|$ defined on $\mathbb{R} \rightarrow \mathbb{R}$ admits as a subdifferential the sign application, defined by :

$$\text{sign}(x) = \begin{cases} \{1\} & \text{if } x > 0 \\ [-1, 1] & \text{if } x = 0 \\ \{-1\} & \text{if } x < 0. \end{cases}$$

Exercise 2.3.2. Determine the subdifferentials of the following functions, at the considered points :

1. In $\mathcal{X} = \mathbb{R}$, $f(x) = \iota_{[0,1]}$, at $x = 0, x = 1$ and $0 < x < 1$.
2. In $\mathcal{X} = \mathbb{R}^2$, $f(x) = \iota_{B(0,1)}$ (closed Euclidian ball), at x such that $\|x\| < 1$ and at x such that $\|x\| = 1$.
3. $\mathcal{X} = \mathbb{R}$,

$$f(x) = \begin{cases} +\infty & \text{if } x < 0 \\ -\sqrt{x} & \text{if } x \geq 0 \end{cases}$$

at $x = 0$, and $x > 0$.

4. $\mathcal{X} = \mathbb{R}^n$, $f(x) = \|x\|$, determine $\partial f(x)$, for any $x \in \mathbb{R}^n$.
5. $\mathcal{X} = \mathbb{R}$, $f(x) = x^3$. Show that $\partial f(x) = \emptyset$, $\forall x \in \mathbb{R}$. Explain this result.

Exercise 2.3.3. Let $f : \mathbb{R}^n \rightarrow \mathbb{R}$, differentiable. Show that: f is convex, if and only if

$$\forall (x, y) \in \mathbb{R}^n \times \mathbb{R}^n, \langle \nabla f(y) - \nabla f(x), y - x \rangle \geq 0.$$

2.4 Operations on subdifferentials

Until now, we have seen examples of subdifferential computations on basic functions, but we haven't mentioned how to derive the subdifferentials of more complex functions, such as sums or linear transforms of basic ones. A basic fact from differential calculus is that, when all the terms are differentiable, $\nabla(f + g) = \nabla f + \nabla g$. Also, if M is a linear operator, then we have the equality $\nabla(g \circ M)(x) = M^* \nabla g(Mx)$. Under qualification assumptions, these properties are still valid in the convex case, up to replacing the gradient by the subdifferential and point-wise operations by set operations. But first, we need to define operations on sets.

Definition 2.4.1 (addition and transformations of sets). Let $A, B \subset \mathcal{X}$. The Minkowski sum and difference of A and B are the sets

$$\begin{aligned} A + B &= \{x \in \mathcal{X} : \exists a \in A, \exists b \in B, x = a + b\} \\ A - B &= \{x \in \mathcal{X} : \exists a \in A, \exists b \in B, x = a - b\} \end{aligned}$$

Let \mathcal{Y} another space and M any mapping from \mathcal{X} to \mathcal{Y} . Then MA is the image of A by M ,

$$MA = \{y \in \mathcal{Y} : \exists a \in A, y = Ma\}.$$

Proposition 2.4.1. Let $f : \mathcal{X} \rightarrow (-\infty, +\infty]$ be a convex function, $g : \mathcal{Y} \rightarrow \mathbb{R}$ a convex differentiable function and $M : \mathcal{X} \rightarrow \mathcal{Y}$ a linear operator.

$$\forall x \in \mathcal{X}, \partial(f + g \circ M)(x) = \partial f(x) + \{M^* \nabla g(Mx)\}$$

Proof. We first show that $\partial f(\cdot) + \{M^*\nabla g(Mx)\} \subseteq \partial(f + g \circ M)(\cdot)$. Let $x \in \mathcal{X}$ and let $\phi \in \partial f(x) + \{M^*\nabla g(Mx)\}$, which means that $\phi = u + M^*\nabla g(Mx)$ where $u \in \partial f(x)$. In particular, the latter subdifferential is not empty, which implies that $x \in \text{dom } f$. By definition of u and convexity of g , for $y \in \mathcal{X}$,

$$\begin{cases} f(y) - f(x) \geq \langle u, y - x \rangle \\ g(My) - g(Mx) \geq \langle \nabla g(Mx), M(y - x) \rangle = \langle M^*\nabla g(Mx), y - x \rangle. \end{cases}$$

Adding the two inequalities,

$$(f + g \circ M)(y) - (f + g \circ M)(x) \geq \langle \phi, y - x \rangle.$$

Thus, $\phi \in \partial(f + g \circ M)(x)$ and $\partial f(x) + M^*\partial g(Mx) \subset \partial(f + g \circ M)(x)$.

For the converse inclusion, let $\phi \in \partial(f + g \circ M)(x)$. By definition of the subdifferential, for all $y \in \mathcal{X}$, $f(y) + g(My) \geq f(x) + g(Mx) + \langle \phi, y - x \rangle$. In particular, for all $h \in [0, 1]$,

$$f(x + h(y - x)) + g(M(x + h(y - x))) \geq f(x) + g(Mx) + h\langle \phi, y - x \rangle.$$

As f is convex, $f(x + h(y - x)) \leq hf(y) + (1 - h)f(x)$ and so, dividing by h ,

$$f(y) \geq f(x) - \frac{1}{h}(g(M(x + h(y - x))) - g(Mx)) + \langle \phi, y - x \rangle.$$

We let h tend to 0 and we obtain $f(y) \geq f(x) + \langle -\nabla(g \circ M)(x) + \phi, y - x \rangle$. Said otherwise, $\phi - \nabla(g \circ M)(x) \in \partial f(x)$. We conclude using the chain rule. \square

When both functions are not differentiable, the previous theorem requires an additional assumption to apply.

Proposition* 2.4.2. *Let $f : \mathcal{X} \rightarrow (-\infty, +\infty]$, $g : \mathcal{Y} \rightarrow (-\infty, \infty]$ two convex functions and let $M : \mathcal{X} \rightarrow \mathcal{Y}$ a linear operator.*

$$\forall x \in \mathcal{X}, \partial f(x) + M^*\partial g(Mx) \subseteq \partial(f + g \circ M)(x)$$

Moreover, if $0 \in \text{relint}(\text{dom } g - M \text{ dom } f)$, then

$$\forall x \in \mathcal{X}, \partial(f + g \circ M)(x) = \partial f(x) + M^*\partial g(Mx)$$

Proof. The general proof is omitted. It makes use of the Fenchel-Young inequality and of the strong duality theorem that will be given in Chapters 5 and 6.

Remark that when g is differentiable, $\text{dom } g = \mathcal{Y}$ and thus the condition is trivially satisfied. \square

2.5 Fermat's rule, optimality conditions.

A point x is called a **minimizer** of f if $f(x) \leq f(y)$ for all $y \in \mathcal{X}$. The set of minimizers of f is denoted $\arg \min(f)$.

Theorem 2.5.1 (Fermat's rule). $x \in \arg \min f \Leftrightarrow 0 \in \partial f(x)$.

Proof. $x \in \arg \min f \Leftrightarrow \forall y, f(y) \geq f(x) + \langle 0, y - x \rangle \Leftrightarrow 0 \in \partial f(x)$. \square

Recall that, in the differentiable, non convex case, a *necessary* condition (not a sufficient one) for \bar{x} to be a local minimizer of f , is that $\nabla f(\bar{x}) = 0$. Convexity allows handling non differentiable functions, and turns the necessary condition into a sufficient one.

Besides, local minima for any function f are not necessarily global ones. In the convex case, everything works fine:

Proposition 2.5.1. *Let x be a local minimum of a convex function f . Then, x is a global minimizer.*

Proof. The local minimality assumption means that there exists an open ball $V \subset \mathcal{X}$, such that $x \in V$ and that, for all $u \in V$, $f(x) \leq f(u)$.

Let $y \in \mathcal{X}$ and t such that $u = x + t(y - x) \in V$. Then using the convexity of f , we get $f(u) \leq tf(y) + (1 - t)f(x)$. Re-organizing, we get

$$f(y) \geq t^{-1}(f(u) - (1 - t)f(x)) \geq f(x).$$

□

Exercise 2.5.1. Let us denote

$$\text{prox}_g(y) = \arg \min_{x \in \mathcal{X}} g(x) + \frac{1}{2} \|x - y\|^2$$

the proximal operator of g at y .

Fix $\gamma > 0$. Show that if f and g are convex, then the fixed points of the nonlinear equation

$$x = \text{prox}_{\gamma g}(x - \gamma \nabla f(x))$$

are the minimizers of the function $F = f + g$.

Chapter 3

Primal methods

3.1 How to compute gradients?

Let $f : \mathbb{R}^n \rightarrow \mathbb{R}$ be a function. We would like to compute its gradient. By definition, $\nabla f(x)$ is the unique vector of \mathbb{R}^n such that

$$f(x+h) = f(x) + \langle \nabla f(x), h \rangle + o(h) .$$

Let us recall three methods to calculate this vector.

3.1.1 Using partial derivatives

We know that the gradient is the vector of all the partial derivatives. Hence, we can compute $\frac{\partial f}{\partial x_i}(x)$ for all i and reconstruct the vector.

Example. Let us consider the function $f(x) = \|Ax - b\|^2$ where $A \in \mathbb{R}^{m \times n}$. We can write

$$f(x) = \sum_{j=1}^m \left(\sum_{i=1}^n A_{j,i} x_i - b_j \right)^2$$

and so

$$\frac{\partial f}{\partial x_k}(x) = 2 \sum_{j=1}^m A_{j,k} \left(\sum_{i=1}^n A_{j,i} x_i - b_j \right) .$$

We recognise the components of the vector

$$\nabla f(x) = 2A^\top (Ax - b) .$$

3.1.2 Using the definition

We compute $f(x+h)$ and try isolating $f(x)$, a term linear in h and a negligible term.

Example. We consider $f(x) = \|Ax - b\|^2$.

$$\begin{aligned} f(x+h) &= \|A(x+h) - b\|^2 = \|Ax - b\|^2 + 2\langle Ax - b, Ah \rangle + \|Ah\|^2 \\ &= f(x) + 2\langle A^\top (Ax - b), h \rangle + o(h) \end{aligned}$$

thus, $\nabla f(x) = 2A^\top (Ax - b)$.

3.1.3 Using the chain rule

Let $g : \mathbb{R}^n \rightarrow \mathbb{R}^m$ and $f : \mathbb{R}^m \rightarrow \mathbb{R}^p$. The chain rule states that the Jacobian matrix of the function $f \circ g$ at x is given by

$$J_{f \circ g}(x) = J_f(g(x)) \times J_g(x) .$$

We recall that

$$J_g(x) = \begin{bmatrix} \frac{\partial g_1}{\partial x_1}(x) & \dots & \frac{\partial g_1}{\partial x_n}(x) \\ \vdots & & \vdots \\ \frac{\partial g_m}{\partial x_1}(x) & \dots & \frac{\partial g_m}{\partial x_n}(x) \end{bmatrix}$$

is the unique linear map such that

$$g(x + h) = g(x) + J_g(x)h + o(h) .$$

The chain rule allows us to combine simple functions in order to obtain complex functions. It is at the basis of automatic differentiation and the resolution of neural network models.

When $f : \mathbb{R}^m \rightarrow \mathbb{R}$ and $g(x) = Ax$ where A is a $m \times n$ matrix, the formula simplifies as

$$\nabla(f \circ A)(x) = A^\top \nabla f(Ax) .$$

Example. We consider $f(x) = \|Ax - b\|^2$.

Let us remark that $f(x) = h(Ax)$ where $h(y) = \|y - b\|^2$.

Since $h(y + h) = \|y + h - b\|^2 = \|y - b\|^2 + 2\langle y - b, h \rangle + \|h\|^2$, we know that $\nabla h(y) = 2(y - b)$.

Using the chain rule, we get $\nabla f(x) = \nabla(h \circ A)(x) = A^\top \nabla h(Ax) = 2A^\top (Ax - b)$.

3.2 Gradient method

3.2.1 Constant step sizes

The gradient method is the most basic optimization method for a differentiable function f . It consists in a sequence $(x_k)_{k \in \mathbb{N}}$ of points in \mathbb{R}^n defined by induction from $x_0 \in \mathbb{R}^n$ by

$$x_{k+1} = x_k - \gamma_k \nabla f(x_k)$$

where for all k , γ_k is a positive coefficient.

Theorem 3.2.1. *Let f be a convex differentiable function that has a minimizer x^* and whose gradient is L -Lipschitz continuous. The gradient method with constant step size $\gamma_k = \frac{1}{L}$ satisfies*

$$f(x_k) - f(x^*) \leq \frac{L\|x_0 - x^*\|^2}{2k}$$

If moreover f is μ -strongly convex, then

$$\begin{aligned} f(x_k) - f(x^*) &\leq \left(1 - \frac{\mu}{L}\right)^k (f(x_0) - f(x^*) + \frac{L}{2}\|x_0 - x^*\|^2) \\ \|x_k - x^*\|^2 &\leq \left(1 - \frac{\mu}{L}\right)^k \left(\frac{2}{L}(f(x_0) - f(x^*)) + \|x_0 - x^*\|^2\right) \end{aligned}$$

Proof. We will prove a more general result in Theorem 3.4.1. □

3.2.2 Line search

Considering constant step sizes makes the proof easier but has drawbacks in practice:

- One needs to compute the Lipschitz constant of the gradient of f , which may be a non-negligible amount of work.
- Some functions, like $(x \mapsto x^4)$ simply do not have a Lipschitz gradient. However, the gradient may be locally Lipschitz.
- Even if the function has a Lipschitz gradient; the estimation of the Lipschitz constant may take into account regions where the curvature is large but that are never visited by the algorithm.

A solution to these three issues is a line search procedure. The idea of line search is to choose γ_k adaptively using local information.

Exact line search. We take

$$\gamma_k = \arg \min_{\gamma \in \mathbb{R}_+} f(x_k - \gamma \nabla f(x_k)).$$

This method is most efficient when we have a closed formula for the 1-dimensional optimization problem.

Taylor-based line search. In the proof of convergence of Theorem 3.4.1, we only need the Lipschitz continuity of ∇f in order to ensure that

$$f(x_{k+1}) = f(x_k - \frac{1}{L} \nabla f(x_k)) \leq f(x_k) + \langle \nabla f(x_k), x_{k+1} - x_k \rangle + \frac{L}{2} \|x_k - x_{k+1}\|^2.$$

The Taylor-based line search chooses a step size γ_k such that for the tentative update defined by $x^+(\gamma_k) = x_k - \gamma_k \nabla f(x_k)$, we have

$$f(x^+(\gamma_k)) \leq f(x_k) + \langle \nabla f(x_k), x^+(\gamma_k) - x_k \rangle + \frac{1}{2\gamma_k} \|x_k - x^+(\gamma_k)\|^2$$

using the following algorithm.

We set $b > 0, a \in (0, 1)$ and we find the first nonnegative integer l such that

$$f(x^+(ba^l)) \leq f(x_k) + \langle \nabla f(x_k), x^+(ba^l) - x_k \rangle + \frac{1}{2ba^l} \|x_k - x^+(ba^l)\|^2 \quad (3.2.1)$$

Then we set $\gamma_k = ba^l$. Clearly, if such an l exists, the desired inequality will hold.

Proposition 3.2.1. *If f has a L -Lipschitz gradient, then the Taylor-based line search will terminate with $l < \frac{\log(ba^{-1}L)}{\log(a^{-1})}$ and $ba^l < aL$*

Proof. If ∇f is L -Lipschitz, then it is also L' -Lipschitz for all $L' \geq L$. Hence, as soon as $1/(ba^l) \geq L$ (which will eventually happen since $1/a > 1$), (3.2.1) will hold and the line search will terminate. Just before, we had $1/(ba^{l-1}) < L$, so, $1/(ba^l) < a^{-1}L$. We get the bound on l by passing to the log. \square

Note that we do not need to know this Lipschitz constant in order to run the line search.

Classical choices for the parameters are $a = 0.5$ and $b = 2\gamma_{k-1}$.

Armijo's line search. This line search is the most famous one. Given $a \in (0, 1)$, $b > 0$ and $\beta \in (0, 1)$, determine the first integer l such that

$$f(x^+(ba^l)) \leq f(x_k) + \beta \langle \nabla f(x_k), x^+(ba^l) - x_k \rangle$$

In the case of gradient descent, $\langle \nabla f(x_k), x^+(\gamma) - x_k \rangle = -\gamma \|\nabla f(x_k)\|^2$ so we can see that the Taylor-based line search is equivalent to an Armijo's line search with $\beta = 1/2$.

3.3 Subgradient method

When the function we want to minimize is not differentiable but is still convex we can use subgradients instead of gradients. In return, we shall set smaller, diminishing step-sizes to ensure that the algorithm continues to converge. The algorithm is quite general but is known to be slow. We obtain the algorithm

Algorithm 1 : Subgradient method

select $g_k \in \partial f(x_k)$

$x_{k+1} = x_k - \gamma_k g_k$

where for all k , γ_k is a positive coefficient.

Proposition 3.3.1. *Let f be a convex function that has a minimizer x^* and γ_k be a sequence such that $\frac{\sum_{i=0}^k \gamma_i^2}{\sum_{i=0}^k \gamma_i} \rightarrow 0$ when $k \rightarrow +\infty$. Then the subgradient method satisfies*

$$f(x_k) - f(x^*) \rightarrow 0$$

3.4 Proximal gradient method

The proximal gradient method is a method designed to solve composite problems of the type

$$\min_{x \in \mathbb{R}^n} f(x) + g(x)$$

where f has a Lipschitz gradient and the proximal operator of g is easy to compute, ideally, prox_g has a closed form. The algorithm is given by

$$x_{k+1} = \text{prox}_{\gamma_k g}(x_k - \gamma_k \nabla f(x_k))$$

for given step sizes $\gamma_k > 0$.

The advantage of this method is to deal with simple non-differentiable functions in a way that preserves the good convergence properties of gradient descent. Indeed, for the problems where the proximal operator of g is easy to compute, the proximal gradient method will be much faster than the subgradient method.

The Taylor-based line search can be generalized to the proximal gradient method. We need to choose γ_k such that for $x^+(\gamma_k) = \text{prox}_{\gamma_k g}(x_k - \gamma_k \nabla f(x_k))$, we have

$$f(x^+(\gamma_k)) \leq f(x_k) + \langle \nabla f(x_k), x^+(\gamma_k) - x_k \rangle + \frac{1}{2\gamma_k} \|x_k - x^+(\gamma_k)\|^2. \quad (3.4.1)$$

Armijo's line search can be generalized in the same way.

Theorem 3.4.1. *Let f be a convex differentiable function whose gradient is L -Lipschitz continuous, g be a convex l.s.c. function and x^* a minimizer of $f + g$. The proximal gradient method with constant step size $\gamma_k = \frac{1}{L}$ satisfies*

$$f(x_k) + g(x_k) - f(x^*) - g(x^*) \leq \frac{L\|x_0 - x^*\|^2}{2k}$$

If moreover f is μ -strongly convex, then denoting $\Delta_0 = f(x_0) + g(x_0) - f(x^) - g(x^*) + \frac{L}{2}\|x_0 - x^*\|^2$,*

$$\begin{aligned} f(x_k) + g(x_k) - f(x^*) - g(x^*) &\leq \left(1 - \frac{\mu}{L}\right)^k \Delta_0 \\ \|x_k - x^*\|^2 &\leq \left(1 - \frac{\mu}{L}\right)^k \frac{2\Delta_0}{L} \end{aligned}$$

To prove this theorem, we begin with a couple of lemmas.

Lemma 3.4.1 (Taylor-Lagrange inequality). *Let $f : \mathbb{R}^n \rightarrow \mathbb{R}$ be a differentiable function whose gradient is L -Lipschitz continuous i.e. $\|\nabla f(y) - \nabla f(x)\| \leq L\|y - x\|$ for all x, y . Then for all x and all y ,*

$$f(y) \leq f(x) + \langle \nabla f(x), y - x \rangle + \frac{L}{2}\|y - x\|^2$$

Proof. We first use Cauchy-Schwartz inequality:

$$\begin{aligned} \langle \nabla f(y) - \nabla f(x), y - x \rangle &\leq |\langle \nabla f(y) - \nabla f(x), y - x \rangle| \leq \|\nabla f(y) - \nabla f(x)\| \cdot \|y - x\| \\ &\leq L\|y - x\|^2 \end{aligned}$$

Set $\varphi(t) = f(x + t(y - x))$ for all $t \in [0, 1]$. It is clear that $\varphi(0) = f(x)$ and $\varphi(1) = f(y)$. Note that $\varphi(t) = f(g(t))$ where $g(t) = x + t(y - x)$. By the theorem of derivation of composite functions,

$$\varphi'(t) = \langle \nabla f(g(t)), g'(t) \rangle = \langle \nabla f(x + t(y - x)), y - x \rangle \quad (3.4.2)$$

So $\varphi'(0) = \langle \nabla f(x), y - x \rangle$. Combining the three equalities yields

$$\varphi(1) - \varphi(0) - \varphi'(0) = f(y) - f(x) - \langle \nabla f(x), y - x \rangle.$$

As φ is a primitive of φ' , $\varphi(1) = \varphi(0) + \int_0^1 \varphi'(t) dt$. Hence, using (3.4.2)

$$\begin{aligned} f(y) - f(x) - \langle \nabla f(x), y - x \rangle &= \varphi(1) - \varphi(0) - \varphi'(0) = \int_0^1 \varphi'(t) dt - \varphi'(0) \\ &= \int_0^1 \langle \nabla f(x + t(y - x)), y - x \rangle dt - \int_0^1 \langle \nabla f(x), y - x \rangle dt \\ &= \int_0^1 \langle \nabla f(x + t(y - x)) - \nabla f(x), y - x \rangle dt \end{aligned}$$

We know that for all x, z , $\langle \nabla f(z) - \nabla f(x), z - x \rangle \leq L\|z - x\|^2$. We use this inequality with $z = x + t(y - x)$: $\langle \nabla f(x + t(y - x)) - \nabla f(x), t(y - x) \rangle \leq L\|t(y - x)\|^2$. Dividing by t and integrating between 0 and 1, we get

$$\int_0^1 \langle \nabla f(x + t(y - x)) - \nabla f(x), y - x \rangle dt \leq \int_0^1 tL\|y - x\|^2 dt = \left[\frac{t^2}{2} \right]_0^1 L\|y - x\|^2 = \frac{L}{2}\|y - x\|^2 \quad \square$$

Lemma 3.4.2. Let $g : \mathbb{R}^n \rightarrow \mathbb{R} \cup \{+\infty\}$ be a convex function whose proximal operator is defined by $\text{prox}_g(x) = \arg \min_{y \in \mathbb{R}^n} g(y) + \frac{1}{2}\|y - x\|^2$. Denoting $p = \text{prox}_{\gamma g}(x)$, we have for all z ,

$$g(p) + \frac{1}{2\gamma}\|x - p\|^2 \leq g(z) + \frac{1}{2\gamma}\|x - z\|^2 - \frac{1}{2\gamma}\|p - z\|^2. \quad (3.4.3)$$

Proof. Note that $(y \mapsto \frac{1}{2}\|y - x\|^2)$ is differentiable, so has full domain. Hence, by Fermat's rule and the definition of p , $0 \in \partial g(p) + \frac{1}{\gamma}\{p - x\}$.

Define the function $h : y \mapsto g(y) + \frac{1}{2\gamma}\|x - y\|^2 - \frac{1}{2\gamma}\|p - y\|^2 = g(y) + \frac{1}{2\gamma}\|x\|^2 - \frac{1}{2\gamma}\|p\|^2 + \frac{1}{\gamma}\langle y, p - x \rangle$. h is convex and $0 \in \partial h(p)$. The inequality is just the fact that p minimizes h . \square

Proof of the theorem. We proceed with the proof of the theorem. Using both lemmas, we get that for any z ,

$$\begin{aligned} f(x_{k+1}) + g(x_{k+1}) &\leq f(x_k) + \langle \nabla f(x_k), x_{k+1} - x_k \rangle + \frac{L}{2}\|x_{k+1} - x_k\|^2 \\ &\quad + g(z) + \frac{L}{2}\|x_k - \frac{1}{L}\nabla f(x_k) - z\|^2 - \frac{L}{2}\|x_{k+1} - z\|^2 - \frac{L}{2}\|x_{k+1} - x_k + \frac{1}{L}\nabla f(x_k)\|^2 \end{aligned}$$

We develop the squared norms involving a $\frac{1}{L}\nabla f(x_k)$ term and we get:

$$f(x_{k+1}) + g(x_{k+1}) \leq f(x_k) + \langle \nabla f(x_k), z - x_k \rangle + g(z) + \frac{L}{2}\|x_k - z\|^2 - \frac{L}{2}\|x_{k+1} - z\|^2$$

By setting $z = x_k$, we obtain $f(x_{k+1}) + g(x_{k+1}) \leq f(x_k) + g(x_k)$.

By setting $z = x^*$, we obtain

$$\begin{aligned} f(x_{k+1}) + g(x_{k+1}) &\leq f(x_k) + \langle \nabla f(x_k), x^* - x_k \rangle + g(x^*) + \frac{L}{2}\|x_k - x^*\|^2 - \frac{L}{2}\|x_{k+1} - x^*\|^2 \\ &\leq f(x^*) + g(x^*) + \frac{L}{2}\|x_k - x^*\|^2 - \frac{L}{2}\|x_{k+1} - x^*\|^2. \end{aligned}$$

We sum for l between 0 and $k - 1$.

$$k(f(x_k) + g(x_k)) \leq \sum_{l=0}^{k-1} f(x_{l+1}) + g(x_{l+1}) \leq k(f(x^*) + g(x^*)) + \frac{L}{2}\|x_0 - x^*\|^2 - \frac{L}{2}\|x_k - x^*\|^2$$

Dividing by k gives the result for the convex case.

We leave the strongly convex case as an exercise. \square

Remark 3.4.1. A slightly better rate can be obtained by taking $\gamma = \frac{2}{L+\mu}$, provided μ is known [Nesterov \(2004\)](#).

3.5 Newton's method

Newton's method uses the Hessian matrix in order to ensure convergence in a smaller number of iterations. As shown in MDI210 – Optimisation et analyse numérique we have a quadratic convergence.

Theorem 3.5.1. If f is three times continuously differentiable and if x_0 is chosen close enough to a local minimum x^* where the Hessian matrix of f is positive definite, then the sequence x_k generated by Newton's method

$$x_{k+1} = x_k - (\nabla^2 f(x_k))^{-1} \nabla f(x_k)$$

converges to x^* and there exists $M > 0$ such that

$$\|x_{k+1} - x^*\| \leq M \|x_k - x^*\|^2.$$

Out of the region of quadratic convergence, Newton's method may diverge. Hence, the method should be combined with a line search procedure similar to (3.4.1) in order to ensure convergence even if x_0 is not close to x^* .

Newton's method with line search is given by

$$\begin{aligned} x^+(\gamma) &= x_k - \gamma (\nabla^2 f(x_k))^{-1} \nabla f(x_k) \\ x_{k+1} &= x^+(\gamma_k) \end{aligned}$$

where $\gamma_k \in]0, 1]$ is such that

$$f(x^+(\gamma_k)) \leq f(x_k) + \langle \nabla f(x_k), x^+(\gamma_k) - x_k \rangle + \frac{1}{2\gamma_k} (x^+(\gamma_k) - x_k)^\top \nabla^2 f(x_k) (x^+(\gamma_k) - x_k).$$

We should also make sure that the line search selects $\gamma_k = 1$ when possible in order to keep the quadratic convergence.

Chapter 4

Stochastic gradient descent

4.1 Algorithm

Let us consider a measurable function

$$\begin{aligned} f : \mathcal{X} \times \Xi &\rightarrow \mathbb{R} \\ (x, t) &\mapsto f(x, t) \end{aligned}$$

and a random variable ξ on the probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with values in Ξ . We suppose that $\mathbb{E}(|f(x, \xi)|) < +\infty$.

The stochastic gradient method has been designed to solve the optimization problem

$$\min_{x \in \mathcal{X}} \mathbb{E}(f(x, \xi)) \quad (4.1.1)$$

The challenge is that the law of ξ is not supposed to be known and we cannot compute \mathbb{E} . Instead, it is revealed through (ξ_k) , a sequence of i.i.d. samples of ξ . Given a sequence of step sizes γ_k , the algorithm reads

$$x_{k+1} = x_k - \gamma_k \nabla f(x_k, \xi_{k+1})$$

where $\nabla f(x_k, \xi_{k+1})$ is the gradient of $(x \mapsto f(x, \xi_{k+1}))$ at x_k .

Remark 4.1.1. If $(x \mapsto f(x, \xi_{k+1}))$ is not differentiable, one can use a subgradient of the function instead of its gradient.

Example 4.1.1 (Empirical Risk Minimization). In this context, we are given N data points, each of which is associated with a loss function f_i , $1 \leq i \leq N$. A typical model in machine learning consists in minimizing the empirical risk given by

$$\min_x \frac{1}{N} \sum_{i=1}^N f_i(x)$$

This corresponds to Problem (4.1.1) with $\xi = I \sim U(\{1, \dots, N\})$. The expectation is computable but N may be so large that this takes a long time. Running stochastic gradient on this problem leads to an algorithm with very low complexity per iteration, which is often used in practice:

$$\begin{cases} \text{Generate } I_{k+1} \sim U(\{1, \dots, N\}) \\ x_{k+1} = x_k - \gamma_k \nabla f_{I_{k+1}}(x_k) \end{cases}$$

Example 4.1.2 (Least Mean Squares). We are given a random variable $\xi = (X, Y)$ where $X \in \mathbb{R}^n$ and $Y \in \mathbb{R}$. Least Mean Squares (LMS) is a regression problem in expectation

$$\min_{w \in \mathbb{R}^n} \frac{1}{2} \mathbb{E}[(Y - X^\top w)^2]$$

Stochastic gradient on this problems writes

$$w_{k+1} = w_k - \gamma_k (X_{k+1}^\top w_k - Y_{k+1}) X_{k+1}$$

This algorithm is also used and analysed when (ξ_k) is not i.i.d. [Macchi and Eweda \(1983\)](#).

4.2 Convergence

We denote $F(x) = \mathbb{E}(f(x, \xi))$.

Theorem 4.2.1. *Suppose that:*

- $(x \mapsto f(x, \xi))$ is convex and differentiable for all ξ ,
- there exists $C > 0$ such that $\mathbb{E}(\|\nabla f(x, \xi)\|^2) \leq C$ for all x
- there exists $x^* \in \arg \min F$,
- the sequence γ_k is deterministic.

The iterates of the stochastic gradient algorithm $x_{k+1} = x_k - \gamma_k \nabla f(x_k, \xi_{k+1})$ satisfy the convergence guarantee

$$\mathbb{E}[F(\bar{x}_k^\gamma) - F(x^*)] \leq \frac{\mathbb{E}[\|x_0 - x^*\|^2] + C \sum_{l=0}^k \gamma_l^2}{2 \sum_{l=0}^k \gamma_l}$$

where $\bar{x}_k^\gamma = \frac{\sum_{l=0}^k \gamma_l x_l}{\sum_{j=0}^k \gamma_j}$ is a convex combination of all previous iterates.

Proof. Let us first remark that $\mathbb{E}[\nabla f(x, \xi)] \in \partial F(x)$ for all x . Indeed,

$$\begin{aligned} f(y, \xi) &\geq f(x, \xi) + \langle \nabla f(x, \xi), y - x \rangle \\ F(y) = \mathbb{E}[f(y, \xi)] &\geq \mathbb{E}[f(x, \xi)] + \mathbb{E}[\langle \nabla f(x, \xi), y - x \rangle] = F(x) + \langle \mathbb{E}[\nabla f(x, \xi)], y - x \rangle. \end{aligned}$$

Now, we denote by \mathbb{E}_k the expectation knowing (ξ_1, \dots, ξ_k) . Note that x_k is measurable with respect to (ξ_1, \dots, ξ_k) , so that

$$\begin{aligned} \mathbb{E}_k[\|x_{k+1} - x^*\|] &= \mathbb{E}_k[\|x_k - x^*\| + 2\langle x_{k+1} - x_k, x_k - x^* \rangle + \|x_{k+1} - x_k\|^2] \\ &= \|x_k - x^*\| - 2\gamma_k \langle \mathbb{E}_k[\nabla f(x_k, \xi_{k+1})], x_k - x^* \rangle + \gamma_k^2 \mathbb{E}_k[\|\nabla f(x_k, \xi_{k+1})\|^2] \\ &\leq \|x_k - x^*\| + 2\gamma_k \langle \mathbb{E}_k[\nabla f(x_k, \xi_{k+1})], x^* - x_k \rangle + \gamma_k^2 C \\ &\leq \|x_k - x^*\| + 2\gamma_k (F(x^*) - F(x_k)) + \gamma_k^2 C. \end{aligned}$$

We reorganise and apply total expectation:

$$\mathbb{E}[\gamma_k (F(x_k) - F(x^*))] \leq -\frac{1}{2} \mathbb{E}[\|x_{k+1} - x^*\|^2] + \frac{1}{2} \mathbb{E}[\|x_k - x^*\|^2] + \frac{\gamma_k^2 C}{2}$$

We sum for l between 0 and k :

$$\mathbb{E}\left[\sum_{l=0}^k \gamma_l (F(x_l) - F(x^*))\right] \leq -\frac{1}{2}\mathbb{E}[\|x_{k+1} - x^*\|^2] + \frac{1}{2}\mathbb{E}[\|x_0 - x^*\|^2] + \sum_{l=0}^k \frac{\gamma_l^2 C}{2}$$

The result follows by convexity of F :

$$\mathbb{E}\left[F(\bar{x}_l^\gamma) - F(x^*)\right] \leq \frac{1}{\sum_{j=0}^k \gamma_j} \mathbb{E}\left[\sum_{l=0}^k \gamma_l (F(x_l) - F(x^*))\right] \leq \frac{\mathbb{E}[\|x_0 - x^*\|^2] + C \sum_{l=0}^k \gamma_l^2}{2 \sum_{j=0}^k \gamma_j} \quad \square$$

4.3 Step size sequence

We know that $\mathbb{E}\left[F(\bar{x}_l^\gamma) - F(x^*)\right] \leq \frac{\mathbb{E}[\|x_0 - x^*\|^2] + C \sum_{l=0}^k \gamma_l^2}{2 \sum_{j=0}^k \gamma_j}$. A natural question is: which sequence (γ_k) should we take?

We would like $\sum_{j=1}^k \gamma_j \rightarrow +\infty$ and $\frac{\sum_{l=1}^k \gamma_l^2}{\sum_{j=1}^k \gamma_j} \rightarrow 0$. Such a sequence can be for instance taken as $\gamma_k = \frac{\gamma_0}{(k+1)^\alpha}$ with $0 < \alpha < 1$. Then,

$$\begin{aligned} \sum_{j=0}^k \gamma_j &= \sum_{j=0}^k \frac{\gamma_0}{(j+1)^\alpha} \geq \sum_{j=0}^k \int_{j+1}^{j+2} \frac{\gamma_0}{t^\alpha} dt = \int_1^{k+2} \frac{\gamma_0}{t^\alpha} dt = \frac{\gamma_0}{1-\alpha} [t^{1-\alpha}]_1^{k+2} = \frac{\gamma_0}{1-\alpha} ((k+2)^{1-\alpha} - 1) \\ \sum_{j=0}^k \gamma_j^2 &= \sum_{j=0}^k \frac{\gamma_0^2}{(j+1)^{2\alpha}} \leq \gamma_0 + \sum_{j=1}^k \int_j^{j+1} \frac{\gamma_0^2}{t^{2\alpha}} dt = \gamma_0 + \int_1^{k+1} \frac{\gamma_0^2}{t^{2\alpha}} dt = \begin{cases} \gamma_0(1 + \ln(k+1)) & \text{if } \alpha = 1/2 \\ \gamma_0(1 + \frac{(k+1)^{1-2\alpha}-1}{1-2\alpha}) & \text{if } \alpha \neq 1/2 \end{cases} \end{aligned}$$

We obtain the following cases:

	$\frac{1}{\sum_{j=0}^k \gamma_j}$	$\frac{\sum_{l=1}^k \gamma_l^2}{\sum_{j=1}^k \gamma_j}$
$0 < \alpha < 1/2$	$O\left(\frac{1}{k^{1-\alpha}}\right)$	$O\left(\frac{1}{k^\alpha}\right)$
$\alpha = 1/2$	$O\left(\frac{1}{k^{1/2}}\right)$	$O\left(\frac{\ln(k)}{k^{1/2}}\right)$
$1/2 < \alpha < 1$	$O\left(\frac{1}{k^{1-\alpha}}\right)$	$O\left(\frac{1}{k^{1-\alpha}}\right)$

The best rate is obtained with $\alpha = 1/2$, that is $\gamma_k = \frac{\gamma_0}{\sqrt{k}}$. With this choice, we have

$$\mathbb{E}[F(\bar{x}_k^\gamma) - F(x^*)] \in O\left(\frac{\ln(k)}{\sqrt{k}}\right).$$

Remark 4.3.1. If we know the number of iterations K we are going to perform, we can set a constant step size $\gamma_k = \frac{a}{\sqrt{K}}$ and obtain a guarantee $\mathbb{E}[F(\bar{x}_K^\gamma) - F(x^*)] \in O\left(\frac{1}{\sqrt{K}}\right)$

Remark 4.3.2. When F is μ -strongly convex, we can show that a step size decreasing as $\gamma_k = \frac{a}{\mu k}$ gives an improved rate $\mathbb{E}[F(\bar{x}_K^\gamma) - F(x^*)] \in O\left(\frac{1}{\mu k}\right)$.

4.4 Nonconvex objective*

Theorem 4.4.1. *Suppose that:*

- *$(x \mapsto f(x, \xi))$ is differentiable for all ξ with a L -Lipschitz gradient,*
- *there exists $C > 0$ such that $\mathbb{E}(\|\nabla f(x, \xi)\|^2) \leq C$ for all x ,*
- *the sequence γ_k is deterministic.*

The iterates of the stochastic gradient algorithm $x_{k+1} = x_k - \gamma_k \nabla f(x_k, \xi_{k+1})$ satisfy the convergence guarantee

$$\mathbb{E} \left[\min_{0 \leq l \leq k} \|\nabla F(x_l)\|^2 \right] \leq \frac{2(F(x_0) - \inf F) + CL \sum_{l=0}^k \gamma_l^2}{2 \sum_{l=0}^k \gamma_l}.$$

Proof. By Taylor-Lagrange inequality,

$$\begin{aligned} F(x_{k+1}) &\leq F(x_k) + \langle \nabla F(x_k), x_{k+1} - x_k \rangle + \frac{L}{2} \|x_{k+1} - x_k\|^2 \\ &\leq F(x_k) - \gamma_k \langle \nabla F(x_k), \nabla f(x_k, \xi_{k+1}) \rangle + \frac{L\gamma_k^2}{2} \|\nabla f(x_k, \xi_{k+1})\|^2 \end{aligned}$$

where we use the fact that $x_{k+1} - x_k = -\gamma_k \nabla f(x_k, \xi_{k+1})$. We apply the conditional expectation \mathbb{E}_k :

$$\begin{aligned} \mathbb{E}_k[F(x_{k+1})] &\leq F(x_k) - \gamma_k \|\nabla F(x_k)\|^2 + \frac{L}{2} \gamma_k^2 \mathbb{E}_k[\|\nabla f(x_k, \xi_{k+1})\|^2] \\ \gamma_k \|\nabla F(x_k)\|^2 &\leq F(x_k) - \mathbb{E}_k[F(x_{k+1})] + \frac{L}{2} \gamma_k^2 C \end{aligned}$$

We then apply total expectation and sum for l between 0 and k

$$\mathbb{E} \left[\sum_{l=0}^k \gamma_l \|\nabla F(x_l)\|^2 \right] \leq F(x_0) - \mathbb{E}[F(x_{k+1})] + \frac{L}{2} \sum_{l=0}^k \gamma_l^2 C$$

The result follows by remarking that $\|\nabla F(x_l)\|^2 \geq \min_{0 \leq l' \leq k} \|\nabla F(x_{l'})\|^2$ for all l and $\mathbb{E}[F(x_{k+1})] \geq \inf F$. \square

Chapter 5

Dual problem

5.1 Lagrangian function

In this chapter, we consider the convex optimization problem

$$\begin{aligned} & \text{minimize over } \mathbb{R}^n : & f(x) \\ & \text{under the constraints : } & g(x) \preceq 0 \\ & & A(x) = 0 \end{aligned} \tag{5.1.1}$$

(i.e. minimize $f(x)$ over \mathbb{R}^n , under the constraint $g(x) \preceq 0$ and $A(x) = 0$), where $f : \mathbb{R}^n \rightarrow (-\infty, \infty]$ is convex and proper; $g(x) = (g_1(x), \dots, g_p(x))$, each $g_i : \mathbb{R}^n \rightarrow \mathbb{R}$ is a convex function ($1 \leq i \leq p$); $A : \mathbb{R}^n \rightarrow \mathbb{R}^m$ is an affine function and $\iota_{g \preceq 0} = \iota_{g^{-1}(\mathbb{R}_-^p)}$.

Using convex indicator functions

$$\iota_C(x) = \begin{cases} 0 & \text{if } x \in C \\ +\infty & \text{if } x \notin C \end{cases}$$

this can also be written as

$$\text{minimize over } \mathbb{R}^n : \quad f(x) + \iota_{g \preceq 0}(x) + \iota_{A=0}(x) . \tag{5.1.2}$$

Under these conditions, the function $x \mapsto f(x) + \iota_{g \preceq 0}(x) + \iota_{A=0}(x)$ is convex.

Definition 5.1.1 (primal value, primal optimal point). The **primal value** associated to (5.1.2) is the infimum

$$p = \inf_{x \in \mathbb{R}^n} f(x) + \iota_{g \preceq 0}(x) + \iota_{A=0}(x).$$

A point $x^* \in \mathbb{R}^n$ is called **primal optimal** if

$$p = f(x^*) + \iota_{g \preceq 0}(x^*) + \iota_{A=0}(x^*).$$

Notice that, under our assumption, $p \in [-\infty, \infty]$. Also, there is no guarantee about the existence of a primal optimal point, and no guarantee that the primal value is attained either.

Since (5.1.2) may be difficult to solve, it is useful to see this as an ‘inf sup’ problem, and solve a ‘sup inf’ problem instead (see definition 5.2.1 below). To make this precise, we introduce the Lagrangian function.

Definition 5.1.2. The **Lagrangian function** associated to problem (5.1.2) is the function

$$\begin{aligned} L : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^p &\longrightarrow [-\infty, +\infty] \\ (x, \phi_E, \phi_I) &\mapsto f(x) + \langle \phi_E, A(x) \rangle + \langle \phi_I, g(x) \rangle - \iota_{\mathbb{R}_+^p}(\phi_I) \end{aligned}$$

(where $\mathbb{R}_+^p = \{\phi \in \mathbb{R}^p, \phi \succeq 0\}$).

The link with the initial problem comes next:

Lemma 5.1.1 (constrained objective as a supremum). *The constrained objective is the supremum (over $\phi = (\phi_E, \phi_I)$) of the Lagrangian function,*

$$\forall x \in \mathbb{R}^n, \quad f(x) + \iota_{g \preceq 0}(x) + \iota_{A=0}(x) = \sup_{\phi \in \mathbb{R}^{m+p}} L(x, \phi)$$

Proof. We give the proof in the case $m = 0$ (only inequality constraints). The general case is similar.

Distinguish the cases $g(x) \preceq 0$ and $g(x) \not\preceq 0$.

(a) If $g(x) \not\preceq 0$, $\exists i \in \{1, \dots, p\} : g_i(x) > 0$. Choosing $\phi_t = te_i$ (where $\mathbf{e} = (e_1, \dots, e_p)$ is the canonical basis of \mathbb{R}^p), $t \geq 0$, then $\lim_{t \rightarrow \infty} L(x, \phi_t) = +\infty$, whence $\sup_{\phi \in \mathbb{R}_+^p} L(x, \phi) = +\infty$. On the other hand, in such a case, $\iota_{g \preceq 0}(x) = +\infty$, whence the result.

(b) If $g(x) \preceq 0$, then $\forall \phi \in \mathbb{R}_+^p, \langle \phi, g(x) \rangle \leq 0$, and the supremum is attained at $\phi = 0$. Whence, $\sup_{\phi \succeq 0} L(x, \phi) = \sup_{\phi \in \mathbb{R}^p} L(x, \phi) = f(x)$.

On the other hand, $\iota_{g \preceq 0}(x) = 0$, so $f(x) + \iota_{g \preceq 0}(x) = f(x)$. The result follows. \square

Equipped with lemma 5.1.1, the primal value associated to problem (5.1.2) writes

$$p = \inf_{x \in \mathbb{R}^n} \sup_{\phi \in \mathbb{R}^{m+p}} L(x, \phi). \quad (5.1.3)$$

One natural idea is to exchange the order of inf and sup in the above problem. Before proceeding, the following simple lemma allows to understand the consequence of such an exchange.

Proposition 5.1.1. *Let $F : A \times B \rightarrow [-\infty, \infty]$ any function. Then,*

$$\sup_{y \in B} \inf_{x \in A} F(x, y) \leq \inf_{x \in A} \sup_{y \in B} F(x, y).$$

Proof. $\forall (\bar{x}, \bar{y}) \in A \times B$,

$$\inf_{x \in A} F(x, \bar{y}) \leq F(\bar{x}, \bar{y}) \leq \sup_{y \in B} F(\bar{x}, y).$$

Taking the supremum over \bar{y} in the left-hand side we still have

$$\sup_{\bar{y} \in B} \inf_{x \in A} F(x, \bar{y}) \leq \sup_{y \in B} F(\bar{x}, y).$$

Now, taking the infimum over \bar{x} in the right-hand side yields

$$\sup_{\bar{y} \in B} \inf_{x \in A} F(x, \bar{y}) \leq \inf_{\bar{x} \in A} \sup_{y \in B} F(\bar{x}, y).$$

up to a simple change of notation, this is the expected result. \square

5.2 Dual problem

Definition 5.2.1 (Dual problem, dual function, dual value).

The **dual value** associated to (5.1.3) is

$$d = \sup_{\phi \in \mathbb{R}^{m+p}} \inf_{x \in \mathbb{R}^n} L(x, \phi_I, \phi_E).$$

The function

$$\mathcal{D}(\phi) = \inf_{x \in \mathbb{R}^n} L(x, \phi)$$

is called the **Lagrangian dual function**. Thus, the **dual problem** associated to the primal problem (5.1.2) is

$$\text{maximize over } \mathbb{R}^{m+p} : \quad \mathcal{D}(\phi).$$

A vector $\lambda \in \mathbb{R}_+^p$ is called **dual optimal** if

$$d = \mathcal{D}(\lambda).$$

Without any further assumption, there is no reason for the two values (primal and dual) to coincide. However, as a direct consequence of Proposition 5.1.1, we have :

Proposition 5.2.1 (Weak duality). *Let p and d denote respectively the primal and dual value for problem (5.1.2). Then,*

$$d \leq p.$$

Proof. Apply Proposition 5.1.1. □

Definition 5.2.2 (Saddle point). Let $F : A \times B \rightarrow [-\infty, \infty]$ any function, and A, B two sets. The point $(x^*, y^*) \in A \times B$ is called a **saddle point** of F if, for all $(x, y) \in A \times B$,

$$F(x^*, y) \leq F(x^*, y^*) \leq F(x, y^*).$$

Proposition 5.2.2. *Let $F : A \times B \rightarrow [-\infty, \infty]$. F has a saddle point (x^*, y^*) if and only if*

$$\sup_{y \in B} \inf_{x \in A} F(x, y) = \inf_{x \in A} F(x, y^*) = F(x^*, y^*) = \sup_{y \in B} F(x^*, y) = \inf_{x \in A} \sup_{y \in B} F(x, y).$$

Proof. Suppose F has a saddle point (x^*, y^*) . As $\forall y, F(x^*, y) \leq F(x^*, y^*)$, we take the supremum in y to get $\sup_{y \in B} F(x^*, y) \leq F(x^*, y^*)$.

$$\begin{aligned} \sup_{y \in B} \inf_{x \in A} F(x, y) &\leq \inf_{x \in A} \sup_{y \in B} F(x, y) && \text{(Prop. 5.1.1)} \\ &\leq \sup_{y \in B} F(x^*, y) && \text{(def of inf)} \\ &\leq F(x^*, y^*) && \text{(saddle point)} \\ &\leq \inf_{x \in A} F(x, y^*) && \text{(saddle point)} \\ &\leq \sup_{y \in B} \inf_{x \in A} F(x, y) && \text{(def of sup)} \end{aligned}$$

Hence all inequalities are equalities and we get the result.

The converse implication is straightforward using the two inner equalities. □

Chapter 6

Strong duality theorem

6.1 Fenchel-Legendre Conjugate*

Definition 6.1.1. Let $f : \mathcal{X} \rightarrow [-\infty, +\infty]$. The **Fenchel-Legendre conjugate** of f is the function $f^* : \mathcal{X}^* \rightarrow [-\infty, \infty]$, defined by

$$f^*(\phi) = \sup_{x \in \mathcal{X}} \langle \phi, x \rangle - f(x), \quad \forall \phi \in \mathcal{X}^*.$$

Notice that

$$f^*(0) = - \inf_{x \in \mathcal{X}} f(x).$$

Figure 6.1 provides a graphical representation of f^* . You should get the intuition that, in the differentiable case, if the maximum is attained in the definition of f^* at point x_0 , then $\phi = \nabla f(x_0)$, and $f^*(\phi) = \langle \nabla f(x_0), x_0 \rangle - f(x_0)$. This intuition will be proved correct in proposition 6.1.2.

Figure 6.1: Fenchel Legendre transform of a smooth function f . The maximum positive difference between the line with slope $\tan(\phi)$ and the graph \mathcal{C}_f of f is reached at x_0 .

Exercise 6.1.1.

Prove the following statements.

General hint: If $h_\phi : x \mapsto \langle \phi, x \rangle - f(x)$ reaches a maximum at x^* , then $f^*(\phi) = h_\phi(x^*)$. Furthermore, h_ϕ is concave (if f is convex). If h_ϕ is differentiable, it is enough to find a zero of its gradient to obtain a maximum.

Indeed, $x \in \arg \max(-h_\phi) \Leftrightarrow 0 \in \partial(-h_\phi)$, and, if $-h_\phi$ is differentiable, $\partial(-h_\phi) = \{-\nabla h_\phi\}$.

1. If $\mathcal{X} = \mathbb{R}$ and f is a quadratic function (of the kind $f(x) = (x - a)^2 + b$), then f^* is also quadratic.
2. In \mathbb{R}^n , let A be a symmetric, definite positive matrix and $f(x) = \langle x, Ax \rangle$ (a quadratic function). Show that f^* is also quadratic.
3. $f : \mathcal{X} \rightarrow [-\infty, +\infty]$. Show that $f = f^* \Leftrightarrow f(x) = \frac{1}{2}\|x\|^2$.

Hint: For the ‘if’ part: show first that $f(\phi) \geq \langle \phi, \phi \rangle - f(\phi)$.

Then, show that $f(\phi) \leq \sup_x \langle \phi, x \rangle - \frac{1}{2}\|x\|^2$. Conclude.

4. $\mathcal{X} = \mathbb{R}$, for

$$f(x) = \begin{cases} 1/x & \text{if } x > 0; \\ +\infty & \text{otherwise .} \end{cases}$$

we have,

$$f^*(\phi) = \begin{cases} -2\sqrt{-\phi} & \text{if } \phi \leq 0; \\ +\infty & \text{otherwise .} \end{cases}$$

5. $\mathcal{X} = \mathbb{R}$, if $f(x) = \exp(x)$, then

$$f^*(\phi) = \begin{cases} \phi \ln(\phi) - \phi & \text{if } \phi > 0; \\ 0 & \text{if } \phi = 0; \\ +\infty & \text{if } \phi < 0. \end{cases}$$

Notice that, if $f(x) = -\infty$ for some x , then $f^* \equiv +\infty$.

Nonetheless, under ‘reasonable’ conditions on f , the Legendre transform enjoys nice properties, and even f can be recovered from f^* (through the equality $f = f^{**}$, see Proposition ??).

Proposition 6.1.1 (Properties of f^*).

Let $f : \mathcal{X} \rightarrow [-\infty, +\infty]$ be any function.

1. f^* is always convex, and l.s.c.
2. If $\text{dom } f \neq \emptyset$, then $-\infty \notin f^*(\mathcal{X})$
3. If f is convex and proper, then f^* is convex, l.s.c., proper.

Proof.

1. Fix $x \in \mathcal{X}$ and consider the function $h_x : \phi \mapsto \langle \phi, x \rangle - f(x)$. From the definition, $f^* = \sup_{x \in \mathcal{X}} h_x$. Each h_x is affine, whence convex. Using proposition 2.1.2, f^* is also convex. Furthermore, each h_x is continuous, whence l.s.c, so that its epigraph is closed. Lemma 2.2.3 thus shows that f^* is l.s.c.
2. From the hypothesis, there is an x_0 in $\text{dom } f$. Let $\phi \in \mathcal{X}$. The result is immediate:

$$f^*(\phi) \geq h_{x_0}(\phi) = f(x_0) - \langle \phi, x_0 \rangle > -\infty.$$

3. In view of points 1. and 2., it only remains to show that $f^* \not\equiv +\infty$. Let $x_0 \in \text{relint}(\text{dom } f)$. According to proposition 2.3.3, there exists a subgradient ϕ_0 of f at x_0 . Moreover, since f is proper, $f(x_0) < \infty$. From the definition of a subgradient,

$$\forall x \in \text{dom } f, \langle \phi_0, x - x_0 \rangle \leq f(x) - f(x_0).$$

Whence, for all $x \in \mathcal{X}$,

$$\langle \phi_0, x \rangle - f(x) \leq \langle \phi_0, x_0 \rangle - f(x_0),$$

thus, $\sup_x \langle \phi_0, x \rangle - f(x) \leq \langle \phi_0, x_0 \rangle - f(x_0) < +\infty$.

Therefore, $f^*(\phi_0) < +\infty$. □

Proposition 6.1.2 (Fenchel-Young). *Let $f : \mathcal{X} \rightarrow [-\infty, \infty]$. For all $(x, \phi) \in \mathcal{X}^2$, the following inequality holds:*

$$f(x) + f^*(\phi) \geq \langle \phi, x \rangle,$$

With equality if and only if $\phi \in \partial f(x)$.

Proof. The inequality is an immediate consequence of the definition of f^* . The condition for equality to hold (i.e., for the converse inequality to be valid), is obtained with the equivalence

$$f(x) + f^*(\phi) \leq \langle \phi, x \rangle \Leftrightarrow \forall y, f(x) + \langle \phi, y \rangle - f(y) \leq \langle \phi, x \rangle \Leftrightarrow \phi \in \partial f(x).$$

□

Exercise 6.1.2. * Let $f : \mathcal{X} \rightarrow (-\infty, +\infty]$ a proper, convex, l.s.c. function. Show that

$$\partial(f^*) = (\partial f)^{-1}$$

where, for $\phi \in \mathcal{X}$, $(\partial f)^{-1}(\phi) = \{x \in \mathcal{X} : \phi \in \partial f(x)\}$.

Hint: Use Fenchel-Young inequality to show one inclusion, and the property $f = f^{**}$ for the other one.

6.2 Equality constraints

Theorem 6.2.1. *Let A be an affine function and f be a convex function. Let us consider the problem with equality constraints*

$$\min_{x \in \mathbb{R}^n} f(x) + \iota_{A=0}(x),$$

the associated Lagrangian

$$L(x, \phi) = f(x) + \langle \phi, A(x) \rangle$$

and the dual problem

$$\sup_{\phi \in \mathbb{R}^m} \mathcal{D}(\phi)$$

where $\mathcal{D}(\phi) = \inf_{x \in \mathbb{R}^n} f(x) + \langle \phi, A(x) \rangle$.

If $0 \in \text{relint}(A(\text{dom } f))$ (constraint qualification condition), then

1. $\inf_{x \in \mathbb{R}^n} f(x) + \iota_{A=0}(x) < +\infty$
2. $\inf_{x \in \mathbb{R}^n} f(x) + \iota_{A=0}(x) = \sup_{\phi \in \mathbb{R}^m} \mathcal{D}(\phi)$ (i.e., the duality gap is zero).
3. (Dual attainment at some λ):

$$\exists \lambda \in \mathbb{R}^m, \text{ such that } d = \mathcal{D}(\lambda).$$

If moreover, $\exists x^ \in \mathbb{R}^n$ such that $\min_{x \in \mathbb{R}^n} f(x) + \iota_{A=0}(x) = f(x^*) + \iota_{A=0}(x^*)$, then (x^*, λ) is a saddle point of L .*

Note that if $\text{dom } f = \mathbb{R}^n$, then the constraints are automatically qualified.

Proof of the theorem, introduction. This proof is a bit technical and should be read only by readers interested in understanding theory deeper.

The idea of the proof is to apply Proposition 2.3.3 on the value function

$$\mathcal{V}(b) = \inf_{x \in \mathbb{R}^n} f(x) + \iota_{\{b\}}(A(x)).$$

Note that $\mathcal{V}(0)$ is the value of the primal problem. \mathcal{V} is convex since it is the infimum of a jointly convex function (Proposition 2.1.3). We are now going to compute \mathcal{V}^* and see its link with the dual function.

Lemma 6.2.1. *For all $\phi \in \mathbb{R}^m$, $\mathcal{V}^*(-\phi) = -\mathcal{D}(\phi)$.*

Proof. For $\phi \in \mathbb{R}^m$, by definition of the Fenchel conjugate,

$$\begin{aligned} \mathcal{V}^*(-\phi) &= \sup_{y \in \mathbb{R}^m} \langle -\phi, y \rangle - \mathcal{V}(y) \\ &= \sup_{y \in \mathbb{R}^m} \langle -\phi, y \rangle - \inf_{x \in \mathbb{R}^n} [f(x) + \iota_{\{y\}}(A(x))] \\ &= \sup_{y \in \mathbb{R}^m} \langle -\phi, y \rangle + \sup_{x \in \mathbb{R}^n} [-f(x) - \iota_{\{y\}}(A(x))] \\ &= \sup_{y \in \mathbb{R}^m} \sup_{x \in \mathbb{R}^n} \langle -\phi, y \rangle - f(x) - \iota_{\{y\}}(A(x)) \\ &= \sup_{x \in \mathbb{R}^n} \left[\sup_{y \in \mathbb{R}^m} \underbrace{\langle -\phi, y \rangle - \iota_{\{y\}}(A(x))}_{\varphi_x(y)} \right] - f(x). \end{aligned} \tag{6.2.1}$$

For a fixed $x \in \text{dom } f$, consider the function $\varphi_x : y \mapsto \langle -\phi, y \rangle - \iota_{\{y\}}(A(x))$. As

$$\varphi(y) = \begin{cases} -\infty & \text{if } y \neq A(x) \\ \langle -\phi, A(x) \rangle & \text{otherwise,} \end{cases}$$

(6.2.1) becomes

$$\begin{aligned} \mathcal{V}^*(-\phi) &= \sup_{x \in \mathbb{R}^n} \langle -\phi, A(x) \rangle - f(x) = - \inf_{x \in \mathbb{R}^n} \underbrace{f(x) + \langle \phi, A(x) \rangle}_{L(x, \phi)} \\ &= -\mathcal{D}(\phi) \end{aligned}$$

□

Corollary 6.2.1. *The dual function \mathcal{D} is concave and upper semi-continuous.*

Proof. Proposition 6.1.1. □

Proof of the theorem, continued. From Lemma 6.2.1, we deduce

$$\begin{aligned} \mathcal{V}^{**}(0) &= \sup_{\phi \in \mathbb{R}^p} -\mathcal{V}^*(\phi) = \sup_{\phi \in \mathbb{R}^p} -\mathcal{V}^*(-\phi) \quad (\text{by symmetry of } \mathbb{R}^p) \\ &= \sup_{\phi \in \mathbb{R}^p} \mathcal{D}(\phi) \end{aligned}$$

Hence, $\mathcal{V}^{**}(0)$ is the value of the dual problem. By Proposition ??, $\mathcal{V}(0) \geq \mathcal{V}^{**}(0)$. Said otherwise, $\inf_{x \in \mathbb{R}^n} f(x) + \iota_{A=0}(x) \geq \sup_{\phi \in \mathbb{R}^p} \mathcal{D}(\phi)$ and we recover weak duality.

Now remark that $\text{dom } \mathcal{V} = \{b \in \mathbb{R}^m : \exists x \in \text{dom } f, A(x) = b\} = A(\text{dom } f)$. So the constraint qualification condition $0 \in \text{relint}(A(\text{dom } f))$ is equivalent to $0 \in \text{relint}(\text{dom } \mathcal{V})$ and we can apply Proposition 2.3.3: $\partial \mathcal{V}(0) \neq \emptyset$.

To show the dual attainment, we take $\lambda \in \partial \mathcal{V}(0) \neq \emptyset$. Equality in Fenchel-Young (Proposition 6.1.2) writes: $\mathcal{V}(0) + \mathcal{V}^*(\lambda) = \langle \lambda, 0 \rangle = 0$. Thus, we have

$$\begin{aligned} \mathcal{V}(0) &= -\mathcal{V}^*(\lambda) \\ &= \mathcal{D}(-\lambda) \\ &\leq \sup_{\phi} \mathcal{D}(\phi) = \mathcal{V}^{**}(0) \leq \mathcal{V}(0) \end{aligned}$$

Hence, all the inequalities are equalities:

$$\inf_{x \in \mathbb{R}^n} f(x) + \iota_{A=0}(x) = \mathcal{V}(0) = -\mathcal{V}^*(\lambda) = \mathcal{D}(-\lambda) = \sup_{\phi} \mathcal{D}(\phi).$$

This shows that the duality gap is 0 and that $-\lambda$ is a dual optimum.

Now, if there exists a primal optimum x^* ,

$$\mathcal{V}(0) = f(x^*) + \iota_{A=0}(x^*) = \sup_{\phi \in \mathbb{R}^m} L(x^*, \phi) \geq L(x^*, -\lambda) \geq \inf_x L(x, -\lambda) = \mathcal{D}(-\lambda)$$

and we conclude using the fact that $\mathcal{V}(0) = \mathcal{D}(-\lambda)$ and Proposition 5.2.2. \square

Remark 6.2.1. The proof shows that the negative subgradients of the value function at 0 are optimal dual points. Hence, we can interpret the optimal dual points as the sensitivity of the primal objective to changes in the constraint.

6.3 Inequality constraints

Theorem 6.3.1. *Let us consider the problem with inequality constraints*

$$\min_{x \in \mathbb{R}^n} f(x) + \iota_{g \leq 0}(x),$$

the associated Lagrangian

$$L(x, \phi) = f(x) + \langle \phi, g(x) \rangle - \iota_{\mathbb{R}_+^p}(\phi)$$

and the dual problem

$$\sup_{\phi \in \mathbb{R}^p} \mathcal{D}(\phi)$$

where $\mathcal{D}(\phi) = \inf_{x \in \mathbb{R}^n} f(x) + \langle \phi, g(x) \rangle - \iota_{\mathbb{R}_+^p}(\phi)$.

If $\exists x_0 \in \text{dom } f$ such that for all j , $g_j(x_0) < 0$ (Slater's constraint qualification condition), then

1. $\inf_{x \in \mathbb{R}^n} f(x) + \iota_{g \leq 0}(x) < +\infty$
2. $\inf_{x \in \mathbb{R}^n} f(x) + \iota_{g \leq 0}(x) = \sup_{\phi \in \mathbb{R}^p} \mathcal{D}(\phi)$ (i.e., the duality gap is zero).
3. (Dual attainment at some λ):

$$\exists \lambda \in \mathbb{R}_+^p, \text{ such that } d = \mathcal{D}(\lambda).$$

If moreover, $\exists x^ \in \mathbb{R}^n$ such that $\min_{x \in \mathbb{R}^n} f(x) + \iota_{g \leq 0}(x) = f(x^*) + \iota_{g \leq 0}(x^*)$, then (x^*, λ) is a saddle point of L .*

Proof. The proof is similar to the equality case. The main difference is in the domain of the value function:

$$\text{dom } \mathcal{V} = \{b \in \mathbb{R}^p : \exists x \in \text{dom } f, g(x) \leq b\}.$$

Slater's condition is exactly saying that $0 \in \text{int dom } \mathcal{V}$. \square

Remark 6.3.1. The Karush-Kuhn-Tucker conditions can be recovered by writing Fermat's rule for the inf-sup conditions and the fact that $\text{dom } g_j = \mathbb{R}^n$ for all j :

$$\begin{aligned} 0 \in \partial_x L(x^*, \phi^*) &= \sum_{j=1}^p \phi_j^* \partial g_j(x^*) + \partial f(x^*) \\ 0 \in \partial_\phi(-L)(x^*, \phi^*) &= -g(x^*) + \partial \iota_{\mathbb{R}_+^p}(\phi^*). \end{aligned}$$

For this second condition, we need to compute $\partial \iota_{\mathbb{R}_+^p}$. First note that for all $\phi \in \mathbb{R}^p$, $\iota_{\mathbb{R}_+^p}(\phi) = \sum_{j=1}^p \iota_{\mathbb{R}_+}(\phi_j)$ and so $\partial \iota_{\mathbb{R}_+^p}(\phi) = \partial \iota_{\mathbb{R}_+}(\phi_1) \times \dots \times \partial \iota_{\mathbb{R}_+}(\phi_n)$. It is a good exercise to show that

$$\partial \iota_{\mathbb{R}_+}(\phi_j) = \begin{cases} \{0\} & \text{if } \phi_j > 0, \\ \mathbb{R}_- & \text{if } \phi_j = 0, \\ \emptyset & \text{if } \phi_j < 0. \end{cases}$$

We obtain that $\forall j$, $g_j(x^*) = 0$ if $\phi_j^* > 0$, $g_j(x^*) \leq 0$ if $\phi_j^* = 0$ and that ϕ_j^* is never strictly negative.

To sum up, at a saddle point (x^*, ϕ^*) , we have

$$\begin{aligned} 0 &\in \sum_{j=1}^p \phi_j^* \partial g_j(x^*) + \partial f(x^*) \\ g(x^*) &\leq 0, \quad \phi^* \geq 0, \quad \langle \phi^*, g(x^*) \rangle = 0 \end{aligned}$$

Exercise 6.3.1 (Examples of duals, [Borwein and Lewis \(2006\)](#), chap.4). Compute the dual of the following problems. In other words, calculate the dual function \mathcal{D} and write the problem of maximizing the latter as a convex minimization problem.

1. Linear program

$$\begin{aligned} &\inf_{x \in \mathbb{R}^n} \langle c, x \rangle \\ &\text{under constraint } Gx \preceq b \end{aligned}$$

where $c \in \mathbb{R}^n$, $b \in \mathbb{R}^p$ and $G \in \mathbb{R}^{p \times n}$.

Hint: you should find that the dual problem is again a linear program, with equality constraints.

2. Quadratic program

$$\begin{aligned} &\inf_{x \in \mathbb{R}^n} \frac{1}{2} \langle x, Cx \rangle \\ &\text{under constraint } Gx \preceq b \end{aligned}$$

where C is symmetric, positive, definite.

Hint : you should obtain an unconstrained quadratic problem.

- Assume in addition that the constraints are linearly independent, *i.e.* $\text{rank}(G) = p$, *i.e.* $G = \begin{pmatrix} w_1^\top \\ \vdots \\ w_p^\top \end{pmatrix}$, where (w_1, \dots, w_p) are linearly independent. Compute then the dual value.

Exercise 6.3.2 (dual gap). Consider the two examples in exercise 6.3.1, and assume, as in example 2., that the constraints are linearly independent. Show that the duality gap is zero under this conditions.

Hint: Slater.

6.4 Examples, Exercises and Problems

In addition to the following exercises, a large number of feasible and instructive exercises can be found in [Boyd and Vandenberghe \(2009\)](#), chapter 5, pp 273-287.

Exercise 6.4.1 (Max-entropy). Let $p = (p_1, \dots, p_n)$, $p_i > 0$, $\sum_i p_i = 1$ a probability distribution over a finite set. If $x = (x_1, \dots, x_n)$ is another probability distribution ($x_i \geq 0$), and if we use the convention $0 \log 0 = 0$, the entropy of x with respect to p is

$$H_p(x) = - \sum_{i=1}^n x_i \log \frac{x_i}{p_i}.$$

To deal with the case $x_i < 0$, introduce the function $\psi : \mathbb{R} \rightarrow (-\infty, \infty]$:

$$\psi(u) = \begin{cases} u \log(u) & \text{if } u > 0 \\ 0 & \text{if } u = 0 \\ +\infty & \text{otherwise .} \end{cases}$$

If $g : \mathbb{R}^n \rightarrow \mathbb{R}^p$, the general formulation of the max-entropy problem under constraint $g(x) \preceq 0$ is

$$\begin{aligned} & \text{maximize over } \mathbb{R}^n \quad \sum_i (-\psi(x_i) + x_i \log(p_i)) \\ & \text{under constraints } \sum x_i = 1; g(x) \preceq 0. \end{aligned}$$

In terms of minimization, the problem writes

$$\inf_{x \in \mathbb{R}^n} \sum_{i=1}^n \psi(x_i) - \langle x, c \rangle + \iota_{\langle \mathbf{1}_n, \cdot \rangle = 1}(x) + \iota_{g \preceq 0}(x). \quad (6.4.1)$$

with $c = \log(p) = (\log(p_1), \dots, \log(p_n))$ and $\mathbf{1}_n = (1, \dots, 1)$ (the vector of size n which coordinates are equal to 1).

A: preliminary questions

1. Show that

$$\partial \iota_{\langle \mathbf{1}_n, \cdot \rangle = 1}(x) = \begin{cases} \{ \lambda_0 \mathbf{1}_n : \lambda_0 \in \mathbb{R} \} := \mathbb{R} \mathbf{1}_n & \text{if } \sum_i x_i = 1 \\ \emptyset & \text{otherwise.} \end{cases}$$

2. Show that ψ is convex

hint: compute first the Fenchel conjugate of the function \exp , then use proposition 6.1.1.

Compute $\partial \psi(u)$ for $u \in \mathbb{R}$.

3. Show that

$$\partial\left(\sum_i \psi(x_i)\right) = \begin{cases} \sum_i (\log(x_i) + 1) \mathbf{e}_i & \text{if } x \succ 0 \\ \emptyset & \text{otherwise,} \end{cases}$$

where $(\mathbf{e}_1, \dots, \mathbf{e}_n)$ is the canonical basis of \mathbb{R}^n .

4. Check that, for any set A , $A + \emptyset = \emptyset$.

5. Consider the unconstrained optimization problem, (6.4.1) where the term $\iota_{g(x) \leq 0}$ has been removed. Show that there exists a unique primal optimal solution, which is $x^* = p$.

Hint: Do not use Lagrange duality, apply Fermat's rule (section 2.5) instead. Then, check that the conditions for subdifferential calculus rules (proposition 2.4.2) apply.

B: Linear inequality constraints In the sequel, we assume that the constraints are linear, independent, and independent from $\mathbf{1}_n$, i.e.: $g(x) = Gx - b$, where $b \in \mathbb{R}^p$, and G is a $p \times n$ matrix,

$$G = \begin{pmatrix} (\mathbf{w}^1)^\top \\ \vdots \\ (\mathbf{w}^p)^\top \end{pmatrix},$$

where $\mathbf{w}^j \in \mathbb{R}^n$, and the vectors $(\mathbf{w}^1, \dots, \mathbf{w}^p, \mathbf{1}_n)$ are linearly independent. We also assume the existence of some point $\hat{x} \in \mathbb{R}^n$, such that

$$\forall i, \hat{x}_i > 0, \sum_i \hat{x}_i = 1, G\hat{x} = b. \quad (6.4.2)$$

1. Show that the constraints are qualified.

Hint: Show that $0 \in \text{int}(G(\Sigma_n) - \{b\} + \mathbb{R}_+^p)$, where $\Sigma_n = \{x \in \mathbb{R}^n : x \succeq 0, \sum_i x_i = 1\}$ is the n -dimensional simplex. In other words, show that for all $y \in \mathbb{R}^p$ close enough to 0, there is some small $\bar{u} \in \mathbb{R}^n$, such that $x = \hat{x} + \bar{u}$ is admissible for problem (6.4.1), and $Gx \leq b + y$.

To do so, exhibit some $u \in \mathbb{R}^n$ such that $Gu = -\mathbf{1}_p$ and $\sum u_i = 0$ (why does it exist?) Pick t such that $\hat{x} + tu \succ 0$. Finally, consider the 'threshold' $Y = -t\mathbf{1}_p \prec 0$ and show that, if $y \succ Y$, then $G(\hat{x} + tu) \leq b + y$. Conclude.

2. Using the KKT conditions, show that any primal optimal point x^* must satisfy:

$$\exists Z > 0, \exists \lambda \in \mathbb{R}_+^p :$$

$$x_i^* = \frac{1}{Z} p_i \exp \left[- \sum_{j=1}^p \lambda_j \mathbf{w}_i^j \right] \quad (i \in \{1, \dots, n\})$$

(this is a Gibbs-type distribution).
